1998 ANNUAL PERFORMANCE REPORT

State of: Idaho | Program: Fisheries Management F-71-R-23

Project I: Surveys and Inventories | Subproject I-D: Southwest Region

Job No.: a | Title: Mountain Lakes Investigations

Contract Period: July 1, 1998 to June 30, 1999

ABSTRACT

A total of 69 mountain lakes in the upper Middle Fork Boise River were visited in 1998. Two fisheries staff personnel conducted one sampling trip. A volunteer leading a string of pack goats provided logistical support for the trip. Eight lakes were gillnetted and five of these lakes were also angled. Two lakes were angled only. Fifty-nine of the lakes visited were classified as "frog ponds" and only observations for the presence of fish and/or amphibians were undertaken. Six lakes contained westslope cutthroat *Oncorhynchus clarki lewisi* and one lake contained rainbow trout *O. mykiss.* Twelve ponds were identified that contained long-toed salamanders *Ambystoma macrodactylum*, four ponds had adult spotted frogs *Rana luteiventris,* and two ponds had juvenile spotted frogs. Many of the ponds were ephemiral and were dry at observation.

Author:

Dale B. Allen
Regional Fishery Manager

METHODS

Alpine lakes, ponds, and marshes were visited to document the distribution of fish and amphibians. Two backpacking fishery staff visited lakes with the support of a volunteer with a string of pack goats. Lake position was determined with a Global Positioning System (GPS) device. Some lakes were sampled with gill nets, some were angled, and some were observed for fish and amphibians. Gill nets were 30.5 m long with 7.6 m panels of 19, 25, 32, and 38 mm square mesh monofilament, and where set, were set overnight. All fish captured in gill nets were measured to the nearest mm and weighed to the nearest g. Lakes were visually surveyed for campsites and signs of human use and notes taken about difficulty of access. Amphibians were documented by walking around the water body, and identifying and counting any amphibians observed. Water quality measurements were taken at some lakes. Data collected was entered into a mountain lakes database and one-page reports were produced on each lake visited.

RESULTS

A total of 69 lakes, ponds, and marshes in the Middle Fork Boise drainage were visited by regional fishery staff in 1998. Gill net sampling only was conducted in eight waters. Seven lakes were angled to capture fish. Fifty-nine of the waters visited were classified as "frog ponds" with only observations for the presence or absence of amphibians noted.

Westslope cutthroat trout *Oncorhynchus clarki lewisi* were found in Confusion, Dandy, Low Pass, Nanny Creek, Queens River #33, and Timpa Lakes. The Queens River #33 lake is not stocked and these fish were naturally produced. Rainbow trout *O. mykiss* were captured only in Blue Jay Lake.

Spotted frog *Rana luteiventris* adult or juveniles were found in six lakes and ponds. Long toed salamanders *Ambystoma macrodactylum* were found in 12 waters.

Summary information for each water containing fish is provided in Appendix A.

Appendix A. **Mountain Lakes General Information**

1998 ANNUAL PERFORMANCE REPORT

State of: Idaho

Program: Fisheries Management F-71-R-23

Project I: Surveys and Inventories

Subproject I-D: Southwest Region

Job No.: b

Title: Lowland Lakes Investigations

Contract Period: July 1, 1998 to June 30, 1999

ABSTRACT

Six regional waters were sampled with a multiple gear lowland lake sampling strategy, which included use of pairs of experimental gill nets, trap nets, and boat electrofishing. C. J. Strike Reservoir, Lake Lowell, Mann Creek Reservoir, Paddock Valley Reservoir, and Red Top Pond were sampled in this manner.

Claytonia Pond and Crane Falls Lake were sampled with boat electrofishing only. Sampling with experimental gill nets only was completed on Deadwood Reservoir and Bull Trout Lake. A combination of trap nets and gill nets were used to sample Lucky Peak Reservoir.

A tag return study was initiated in Mann Creek Reservoir to document the angler return of stocked hatchery catchable rainbow trout *Oncorhynchus mykiss*. A total of 900 fish were tagged of the 10,000 rainbow trout stocked in 1998. Signs were placed at the reservoir explaining how to return the information and drop boxes were provided at the two boat ramps. No rewards were offered for return of the tag information. Over a 20-month period only 12.9% of the tags were returned.

A cooperative project with the U. S. Bureau of Reclamation (BOR) was undertaken at Deadwood Reservoir to further document the status of the bull trout *Salvelinus confluentus* population in the reservoir. Early spring trapnetting was conducted in the reservoir. Two of the main tributary streams, Wild Buck and Basin creeks, had weirs and traps installed to document any up or downstream movement of bull trout. Two bull trout were captured in the reservoir trap net sampling and no bull trout were captured in the tributary weirs.

Creel surveys were conducted at Bull Trout Lake and Martin Lake by U. S. Forest Service "camp hosts" from July to September 1998. Bull Trout Lake anglers expended an estimated 3,020 hours and harvested an estimated 49.6% of the stocked rainbow trout. Martin Lake anglers fished an estimated 1,276 hours and harvested an estimated 87.2% of the stocked rainbow trout.

METHODS

General Fish Sampling

Electrofishing was conducted from a boom-mounted electrofishing boat. Netting of immobilized fish was conducted with one or two netters. Electrofishing was conducted along the shoreline. Attempts were made to collect all fish immobilized. One unit of electrofishing effort was defined as one hour of activated electrode time. Unless noted below, electrofishing occurred during darkness. Electrofishing catch-per-unit of effort (CPUE) was defined as catch, by both number and weight, per hour of activated electrode time.

Gillnetting used floating and sinking experimental gill nets. Experimental gill nets were 45.7 m long by 1.8 m deep, and were composed of 6-7.6 m panels of 1.9, 2.5, 3.2, 3.8, 5.2 and 6.4 cm bar mesh. Nets were set in late afternoon and pulled the following morning. Nets were set by tying or anchoring one end of the net near or on shore in water less than 0.5 m deep and extending the net toward the center of the water, perpendicular to shore. When more than one floating or one sinking net was used per water, nets were set such that both large and small mesh ends of the nets were set next to shore. One unit of gill net effort was defined as one floating and one sinking experimental gill net fished overnight. Gill net CPUE was calculated as combined catch of one floating and one sinking experimental net, by both number and weight, per night. (Hereafter, gill net catch refers to combined catch from one floating and one sinking experimental gill net.)

Trapnetting was conducted using standard trap nets composed of two light steel frames measuring 1.8 m x .9 m, covered with 19 mm square black mesh, and with five 76 cm steel round hoops with crow foot throats on the first and third hoops, and with 23 m long lead lines 0.9 to 1.3 m in height. Trap nets were set on shallow sloping areas with the top of the steel frame within 0.3 m of the water surface. The lead line was tied to shore. Trap nets were set late in the afternoon and pulled the following morning. One unit of trap net effort was defined as one trap net fished overnight. Trap net CPUE was calculated as catch of one trap net, by both number and weight, per night.

Attempts were made to measure a sample of each cm size group of each species collected to the nearest mm and to weigh a sample of each size group collected to the nearest g. In some cases, scale samples were collected to estimate age and growth. Scales from trout were collected from above the lateral line posterior to an imaginary line between the posterior end of the dorsal fin and the anterior end of the anal fin. Scales from bass were collected at the end of the pectoral fin as it lay against the body of the fish from above the lateral line. Fins and scales were placed in labeled envelopes and processed later in the lab.

General Data Analysis

Data from all sampled waters are summarized in the attached appendices. Appendix A is a summary of all types and amounts of sampling effort for each individual date that a body of water was investigated. Multi-gear Lowland Lake sampling events are summarized in Appendix B. Catch-per-unit-effort is calculated by individual gear and then by a standard unit of catch for both number and weight of fish. Appendix C includes a summary of all fish numbers, lengths,

weights, condition factors and percentage of catch by species at any given sampling event. Length frequencies summed by cm group of all captured fish species for all sampled waters are included in Appendix D.

RESULTS

C.J. Strike Reservoir

Lowland Lake Sample

A standard lowland lake survey was conducted on April 2, 1998 utilizing 0.75 h of electrofishing, two trap nets and two pairs of floating and sinking gill nets. The water temperature was 12.5°C at 1615 h. The air temperature and local weather was approximately 5° C with high winds and scattered rain showers. Gillnetting was repeated on June 23, 1999 using three pairs of experimental gill nets and three trap nets to specifically address the status of stocked hatchery rainbow trout. The water temperature was 17.5°C during the June collection efforts. Results of the lowland lake sample and the June netting will be reported separately.

Captured gamefish included smallmouth bass *Micropterus dolomieui*, largemouth bass *Micropterus salmoides*, yellow perch *Perca flavescens*, hatchery rainbow trout *Oncorhynchus mykiss*, bluegill *Lepomis macrochirus*, white crappie *Pomoxis annularis*, black crappie *Pomoxis nigromaculatus*, channel catfish *Ictalurus punctatus*, and brown bullhead *Ameiurus nebulosus*. Non-game species collected included bridgelip sucker *Catostomus columbianus*, largescale sucker *Catostomus macrocheilus*, peamouth *Mylocheilus caurinus*, chiselmouth *Acrocheilus alutaceus*, northern pikeminnow *Ptychocheilus oregonensis*, redside shiner *Richardsonius balteatus*, and common carp *Cyprinus carpio*.

April Lowland Lake Sample

Smallmouth Bass

Eleven smallmouth were captured for a total CPUE by number and weight of 13 and 8.27 kg, respectively. A majority of the smallmouth was collected while electrofishing. Our total catch ranged in size from 211 mm to 523 mm. The mean length of smallmouth captured while electrofishing was 328 mm. Electrofishing conducted in May of 1997 resulted in the capture of 20 times more smallmouth (Allen et al. 2000). Water temperature, local weather, and time of year may have all contributed to a lower catch in 1998.

Largemouth Bass

Only one largemouth bass was collected. Although 14 largemouth bass were collected while electrofishing in 1997, it appears past efforts to enhance the population through supplemental stocking and habitat augmentation is having little effect. On numerous occasions regional fisheries staff have contributed to such projects with volunteers and have tried to explain the fundamental limitations of C.J. Strike Reservoir as a largemouth bass fishery. Nonetheless, interest in continuing the stocking and habitat improvement projects re-emerge annually from organized bass fishing clubs.

Yellow Perch

A majority of the yellow perch collected was caught while trapnetting and gillnetting. The perch ranged in length from 124 mm to 305 mm, with a mean of 192 mm. With yellow perch representing nearly 30% of our total catch, C.J. Strike Reservoir should be an excellent source of perch for anglers in 1999.

Hatchery Rainbow Trout

A total of 20 hatchery rainbow trout were captured. The rainbow trout ranged in length from 117 mm to 262 mm, with a mean of 166 mm. All captured rainbow trout appear to be from recent stocking. There have been a considerable number of angler inquiries during the past year concerning poor trout fishing. The absence of larger rainbow trout might indicate poor fingerling carryover.

Bluegill

Only three bluegill were captured, ranging in length from 43 mm to 130 mm. Although our 1998 catch only represented 3.3% of the total bluegill collected in 1997, weather and sampling one-month earlier than 1997 likely affected our catch (Allen et al. 2000). We suspect the multiple strong year classes we observed while electrofishing in 1997 will provide angling opportunities very similar to those in the last several years.

White Crappie

White crappie ranged in length from 102 mm to 284 mm. Although each gear type captured white crappie, a vast majority was caught while gillnetting. The mean length for the crappie caught in gill nets was 129 mm. We predict good fishing for white crappie for the next several years.

Black Crappie

A total of 11 black crappie were captured and ranged in length from 112 mm to 244 mm.

Channel Catfish

Our catch was limited to two, with lengths of 612 mm and 643 mm. Although we were unable to collect smaller channel catfish, sampling conducted in late May of 1997 indicated that other year classes were present (Allen et al. 2000). Our low catch was likely a result of the cool water temperatures during collection efforts. Angling for channel catfish in 1998 should be very similar to 1997.

June Gillnetting and Trapnetting

Yellow Perch

Multiple year classes of yellow perch were collected. The perch ranged in length from 120 mm to 270 mm, very similar to the results of our April lowland lake survey.

Hatchery Rainbow Trout

Only two hatchery rainbow trout were captured. Their lengths were 310 mm and 343 mm. Anglers continue to report poor success in catching rainbow trout. Although we were unable to collect many rainbow trout, the length of the captured fish suggests there was some carryover from 1997 stocking. In 1999 we will tag 4,000 rainbow trout for planting in C.J. Strike to determine which stocking locations have the best rate of return, and to determine when and where the fish are harvested.

White Crappie

A total of 222 white crappie were collected. They ranged in size from 65 mm to 330 mm. We have received mixed reports from anglers, ranging from fair to excellent harvest of crappie.

Channel Catfish

Our catch increased approximately nine times over our April survey results. A total of 19 were captured, ranging in length from 213 mm to 680 mm. Due to their large mean weight of 1,601 g, channel catfish represented 58% of our total net catch by weight. The increased catch as compared to the April sampling is probably a result of the 5°C warmer water temperature measured in July.

Lake Lowell

Lowland Lake Sample

Sampling was conducted on April 9, 1998 utilizing 1.25 h of electrofishing, two units of gillnetting and three units of trapnetting. In addition, 0.75 h of electrofishing was conducted September 30, 1998.

A total of 343 and 158 fish were collected during April and September sampling, respectively. Black crappie, bluegill, bridgelip sucker, brown bullhead, channel catfish, chiselmouth, common carp, hatchery rainbow, lahontan cutthroat trout *Oncorhynchus clarki henshawi*, largemouth bass, largescale sucker, northern pikeminnow, smallmouth bass and yellow perch were represented in the sampling. Nongame species represented 67% of the total catch during the April sample. During September electrofishing, nongame species comprised 15% of the sample.

Lahontan Cutthroat

Lahontan cutthroat represented the most abundant game fish sampled by numbers and weight during April, with a CPUE of 17 fish and 8.5 kg. The Lahontan cutthroat trout sampled were primarily older fish, from 360 to 460 mm. Hatchery releases of Lahontan cutthroat trout have been made since 1995 (Table 1). No Lahontan cutthroat trout were collected during the September sample. Anglers have begun to target these fish during the period of May and June.

Largemouth Bass

The April sampling appears to have been too early to adequately sample largemouth bass due to cold water temperatures. The CPUE was seven fish, and only one bass less than

180 mm was collected. During September the CPUE for largemouth bass was 158 fish for electrofishing only, compared to the CPUE of 7 for all three gear types used during April. Age 0+, 1+, and 2+ bass were well represented in the September sample, indicating successful spawning occurred the past 3 years and bass had good over winter survival during 1996-97.

Smallmouth Bass

Sampling results for smallmouth bass were similar to largemouth. April sampling was likely too early for meaningful results, with a CPUE of only two fish collected. In the September sample smallmouth CPUE was 76 fish. Age 0+ and 1+ bass were well represented in the sample indicating successful spawning during 1998 and over winter survival during 1997-98.

Bluegill

Bluegill was poorly represented in the April sample. In the September sample, CPUE was 65 fish. Age 1+ bluegill were represented in the sample indicating over winter survival. No bluegill over 150 mm was collected during either sampling period.

Yellow Perch

Yellow perch CPUE was 16 fish during the April sample but were not adequately sampled during September. The perch collected were small, with only two fish greater than 200 mm. The presence of age 1+ and older perch during April indicates successful over winter survival.

Black Crappie

Black crappie was present in both spring and fall samples but only in low numbers. Some crappie larger than 200 mm were sampled. These larger crappie should be mature and spawn during 1998 and 1999.

Repeated requests from anglers to continue black crappie introduction into Lake Lowell culminated in a volunteer hook-and-line collection effort at Owyhee Reservoir in Oregon. Collection occurred in late April and resulted in the transfer of approximately 2,500 crappie to Lake Lowell. Future sampling to evaluate the success of this transfer is planned for 2000.

Mann Creek Reservoir

Mann Creek Reservoir is located approximately 13 km north of Weiser, Idaho. The USBOR dam was completed in 1967 and surface area is 115 ha. Storage is primarily for irrigation but water recreation is popular. A 305 mm minimum length limit for bass has been in effect in the reservoir since 1986. Approximately 10,000 catchable rainbow trout are released into the reservoir each year.

Hatchery Trout Evaluation

A tag return study was initiated during 1998 in Mann Creek Reservoir to document the angler harvest of hatchery catchable rainbow trout (200 to 250 mm in size). A total of 900 tags were placed on 10,000 rainbow trout over five stocking dates during 1998 (Table 2). Signs were

placed around the reservoir alerting anglers about the presence of jaw tags and asking for their assistance. Angler tag returns were voluntary, with no reward offered.

Anglers returned a total of 116 tags for an overall harvest rate of 12.9% for the period from initial hatchery release on March 23, 1998 through reporting cutoff on October 31, 1999. Return rates were highest for the release dates during April, May and September (Table 4). Returns were lowest for the March release and intermediate for the October release. Twenty-one (18% of all tag returns) tagged rainbows were captured as holdover fish during 1999, primarily during March through May. Voluntary tag returns by anglers result in an estimated 40-60% return rate of the actual number of tagged fish harvested (Nichols et al. 1991). Therefore, to estimate the total exploitation rate of hatchery rainbow trout we doubled (50% voluntary compliance of tag returns) the actual number of tag returns we received. The resulting estimate of total return to the creel of hatchery trout released in 1998 equaled 25.8%. The 1996-2000 Department Fish Management Plan calls for 40% return to creel for hatchery catchable rainbow. We did not achieve that goal based on the 1998 evaluation. An overall return rate of over 30% could be achieved by managing the fish releases to occur only during April, May and September.

Lowland Lake Sample

Sampling was completed on April 17, 1998 utilizing one h of electrofishing, two units of gill nets and three units of trap nets. Water temperature was 10°C at 0800 hours.

A total of 393 game fish were collected. Black Crappie, wild and hatchery rainbow trout, largemouth bass, and bridgelip sucker were represented in the catch. The overall sample was similar to sampling completed during 1995 (Allen et al. 1998). The CPUE for game fish was 249 during 1998 compared to 264 during 1995. Bridgelip suckers were collected but remained a minor portion of the biomass sampled similar to 1990 (Grunder et al. 1993).

Wild Rainbow (redband) Trout

Wild rainbow trout *Oncorhynchus mykiss gairdneri* were the most numerous species sampled during 1998. Total CPUE had increased from 39 wild rainbow in 1995 (Allen et al. 1998) to 143 during 1998. Large numbers of age 1+, and age 2+ rainbows were present in the sample during 1998. The increase in wild rainbow trout coincided with above normal precipitation from 1995 to 1998. Natural recruitment from upper Mann Creek represents a significant source of rainbow trout to the reservoir fishery.

Hatchery Rainbow Trout

Total CPUE for hatchery rainbow trout was 44. The initial hatchery release during 1998 was March 23. Therefore, our sample probably reflects a large number of these recently released hatchery trout. Few hatchery trout larger than 300 mm were sampled, indicating limited carryover survival from 1997 releases.

Black Crappie

Black Crappie were the second most numerous species sampled in 1998. The CPUE by number and weight was 49 fish and 4.6 kg, respectively. Crappie had declined compared to 1995 sampling (CPUE of 130 fish and 14.0 kg) (Allen et al. 1998). Mean length of crappie during 1998 equaled 177 mm compared to 188mm and 250 mm during 1995 and 1990,

respectively. Water temperature at the time of sampling may have contributed to the lower catch during 1998.

Largemouth Bass

The CPUE for largemouth bass was 28 fish and 20.9 kg. During 1995, CPUE for bass was 55 fish and 13.0 kg (Allen et al. 1998). Electrofishing CPUE indicates largemouth numbers have steadily declined from samples beginning in 1990. Electrofishing CPUE was 79, 54 and 28 bass for samples collected during 1990, 1995 and 1998, respectively. Based on aging data from 1995 (Allen et al. 1998), few of the bass sampled during 1998 were younger than age 4+ (241 mm). Mean length for largemouth bass sampled during 1998 equaled 336 mm. Sampling during 1998 occurred during April with water temperatures near 10° C compared to sampling in 1990 and 1995 that occurred during June with water temperatures in excess of 15° C. The lower water temperatures during 1998 may have reduced largemouth bass CPUE.

Paddock Reservoir

Lowland Lake Sample

Sampling was conducted on April 22, 1998 utilizing one h of electrofishing, two pairs of gill nets and three trap nets. Water temperature was 16° C at 1600 hours.

A total of 467 fish were captured. The total catch was similar to fall 1997 sampling and about double the catch of April 1997 (Allen et al. 2000). Bluegill, brown bullhead, and largemouth bass represented the majority of the catch. Additionally, six pumpkinseed *Lepomis gibbosus* and two hatchery rainbow trout were captured. Hatchery rainbow (surplus steelhead smolts) disappeared from the sample compared to April and October 1997 samples. These fish were either harvested during 1997 or did not survive well through the 1997-1998 winter.

Bluegill

Bluegill CPUE by number was 158, down from fall 1997 sampling (CPUE = 218) but above the CPUE of 33 observed during April 1997. Smaller sized bluegill of probable age 1+ and age 2+ were well represented in the sample.

Brown Bullhead

The CPUE for brown bullhead was 15 and we sampled bullheads from 240 to 370 mm.

Largemouth Bass

During 1998 we observed a strong year class of age 2+ largemouth bass for the first time since 1995 (Allen et al. 2000). As a result of these smaller fish in our sample, the CPUE (331) was the highest observed since restocking in 1993. A dominant year class of bass (310-350 mm) is still present in the population. Anglers harvested more legal bass (305 mm minimum size) during 1998 as this year class recruited into the fishery. Unlike sampling during 1996 and 1997, our data from 1998 does not indicate predation by larger bass is limiting recruitment of age 0+ bass in Paddock Reservoir.

Black Crappie

No black crappie were sampled during 1998. During 1993, crappie were reintroduced into Paddock Reservoir following drought conditions from 1987 to 1992. Restocking in 1993 included 1,400 crappie, 1,168 bluegill, and 432 largemouth bass. Our sampling during 1998 would indicate the 1993 crappie reintroduction was not successful. Volunteer anglers collected crappie from Owyhee Reservoir, Oregon during 1998 for supplemental stocking into Idaho waters. The effort resulted in the release of 2,500 pre-spawned black crappie into Paddock Reservoir during late April. These fish should have spawned during 1998.

Redtop Pond

Lowland Lake Sampling

Redtop Pond is a 14 ha pond located 7.5 km northwest of Caldwell, Idaho. It is a prior gravel pit source, owned by Idaho Department of Transportation. The Department began management of the pond through a 5-year lease beginning January 1, 1998. It is currently managed as a warmwater fishery with walk in access to the general public.

Sampling was conducted on October 15, 1998 utilizing 0.5 h of electrofishing, two pairs of gill nets and two trap nets. This was the initial inventory of fish populations in Redtop Pond.

A total of 470 game fish were captured. Largemouth bass, brown bullhead, bluegill, pumpkinseed, and black crappie represented 59%, 19%, 6%, 8%, and 7% of the sample, respectively. Natural reproduction during 1998 occurred for largemouth bass, bluegill, and black crappie as evidenced by a high numbers of young-of-the-year (YOY) fish. Although no small brown bullhead were captured, a large number of mature fish (280-320 mm) were captured and natural reproduction is expected. No nongame fish were collected.

Claytonia Pond

Electrofishing

In November 1991, the Department purchased 16 ha of land from Idaho Department of Transportation approximately 3 km northwest of Marsing, Idaho. In 1993 a gravel pit located on the parcel was enlarged, subsequently filled with water and stocked with warmwater game fish. It was named Claytonia Pond and is currently managed as a sportsman's access with a warmwater fishery. It is approximately 14 ha in surface area. It is maintained by ground water and also receives irrigation return water.

Sampling was conducted October 1, 1998 utilizing 0.5 h of electrofishing effort. We collected a total of 148 fish. Species sampled included largemouth bass, bluegill, pumpkinseed, black crappie, yellow perch (1 fish) and common carp. Mean size of fish collected was 140, 120, 150, and 100 mm for black crappie, bluegill, largemouth bass, and pumpkinseed, respectively. Few game fish exceeded 150 mm (6 inches). Carp made up only 9% of the sample by number but 85% by weight. A population renovation to eliminate the carp population is planned during spring, 1999.

Crane Falls Lake

Electrofishing

Sampling was conducted on June 10, 1998 utilizing 0.59 h of energized field time. One netter and one boat operator collected the sample from the entire northern shoreline that paralleled the Snake River. Collection efforts and sampling conditions were very similar to those in the survey conducted in 1994 (Allen et al. 1995).

A total of 661 game fish were sampled. Largemouth bass, bluegill, hatchery rainbow trout, black crappie, pumpkinseed, and yellow perch were represented in the sample.

Bluegill

Bluegill were the most abundant species collected. The 1998 electrofishing CPUE for bluegill was six times the rate observed in 1994, 369 versus 55, respectively. The mean length and weight of individual bluegill was very similar to the 1994 results.

Largemouth Bass

A total of 83 largemouth were collected. The mean length of our largemouth catch was slightly less than observed in 1994, 243 mm and 267 mm, respectively. The CPUE by number for 1994 and 1998 was 105 and 139, respectively. Our bluegill catch indicates abundant forage for largemouth bass is present.

Hatchery Rainbow Trout

The electrofishing CPUE for hatchery rainbow trout was 10.07. All of our catch appeared to have been stocked in either the fall of 1997 or the spring of 1998. Historical electrofishing efforts produced very similar catches in terms of size and quantity.

Black Crappie

A total of three black crappie were collected. Historical electrofishing efforts produced very similar catches in terms of size and quantity.

Pumpkinseed

A total of 41 pumpkinseed were captured. The CPUE by number and mean size was 55 and 129 mm, respectively. In 1994 the CPUE by number and mean size was very similar at 55 and 120 mm, respectively. Although these fish are providing a very limited fishery directly, they appear to make up a significant portion of the Crane Falls largemouth bass diet. After several largemouth bass emptied their stomachs in our livewell, numerous partially digested pumpkinseed were observed.

Yellow Perch

There was an eleven-fold decrease between the observed CPUE for yellow perch in 1998 and 1994, 29 versus 359, respectively. The mean length increased from 97 mm in 1994 to 119 mm in 1998.

Deadwood Reservoir

Gillnetting

Two pairs of experimental gill nets were set in Deadwood Reservoir on October 7, 1998 and pulled the following morning.

Gill nets captured hatchery rainbow trout, kokanee *Oncorhynchus nerka kennerlyi*, mountain whitefish *Prosopium williamsoni*, rainbow/cutthroat hybrid, and westslope cutthroat *Oncorhynchus clarki lewisi*.

There has been some discussion concerning the usefulness of annual fall gillnetting in Deadwood as a management tool, especially in terms of managing kokanee. As an alternative, we are considering concentrating on examining spawning fish during August egg collection activities and discontinuing fall gillnetting in 1999. Netting to monitor other species will be conducted in the spring, possibly on a semi-annual basis.

Kokanee

Kokanee were the most abundant species captured and represented 45.6 % and 32.5% of the total catch by number and weight, respectively. Kokanee ranged in length from 190 mm to 345 mm and had a mean length of 258 mm. The observed mean length follows the increasing trend of fall collected samples since a low of 196 mm in 1992 (Allen et al. 1995). Attempts to control access to major spawning tributaries from 1991 to present, pelagic predator introductions starting in 1991 which included Atlantic salmon *Salmo salar* and fall chinook salmon *Onchorhychus tshawytscha,* and several rotenone treatments of spawning tributaries in 1992 appear to be having an effect on the mean length of spawning kokanee (Allen et al. 1996). Communications with anglers indicated they thought large kokanee were more abundant than in past years. During July and August of 1998 we received numerous angler reports of "excellent" kokanee fishing, with claimed creel limits that averaged approximately 360 mm in length. These reports were similar to size in spawning escapement, which averaged 365 mm in 1998. It remains to be seen if adjustments will need to be made to kokanee adult escapement, or pelagic predator escapement to maintain size and numbers of spawners.

Hatchery Rainbow

A total of five hatchery rainbow were collected. The fish ranged in length from 245 mm to 360 mm, with a mean length of 309 mm.

Westslope Cutthroat

The mean length and total number of westslope cutthroat captured was 327 mm and two, respectively. The lengths were 240 mm and 400 mm. Although the stocking of westslope cutthroat fingerlings was discontinued in 1992, netting catches have been very consistent in the years since and indicate natural reproduction is occurring.

Bull Trout Lake

Bull Trout Lake was sampled on June 6, 1998 with two pair of floating and sinking gill nets. The lake was full and had a water temperature of 13.5° C at noon.

A total of 164 game fish were collected. Brook trout *Salvelinus fontinalis*, kokanee, and fall chinook salmon were represented in the sample.

Brook Trout

Brook trout dominated our catch by weight and total number. The gill net CPUE was 72. Brook trout averaged 190 mm in length, with a range of 75 mm to 317 mm. Gillnetting conducted in 1991 and 1992 resulted in very similar catches, 183 mm average ranging from 110 mm to 290 mm, and 189 mm average ranging from 150 mm to 270 mm (Holubetz et al. 1994, Allen et al. 1995b).

Kokanee Salmon

A total of 19 kokanee were captured. The minimum, maximum, and mean length of kokanee was 160 mm, 185 mm and 172 mm. Kokanee are not currently stocked in Bull Trout Lake. Evidently the population that exists is a residual of past stocking, but no such stocking could be found in the historical records. No kokanee were captured while gillnetting in 1991 or 1992.

Fall Chinook Salmon

Between 1984 and 1996 the Department planted 2,050 fall chinook to reduce brook trout numbers while providing anglers an opportunity to catch a large predator. Only one fall chinook was collected while gillnetting in 1998. Based on a comparison of the length frequencies of captured brook trout since 1991, the brook trout population appears relatively unaffected by the predator introduction.

Lucky Peak Reservoir

Gillnetting and Trapnetting

Lucky Peak was sampled utilizing two pairs of gill nets and three trap nets. All nets were set on the evening of May 6, 1998, and pulled the following morning. The weather at the time of sampling was unsettled with high winds and scattered rain showers. The reservoir was approximately two-thirds full.

A total of 56 game fish were collected. Mountain whitefish, hatchery rainbow trout, smallmouth bass, yellow perch, wild rainbow (redband) trout, and fall chinook salmon were represented in the catch. Non-game species collected included bridgelip sucker, chiselmouth, largescale sucker, northern pikeminnow, redside shiner, and tui chub *Gila bicolor*. Yellow perch was the only gamefish caught in the trap nets.

Hatchery Rainbow Trout

A total of 10 hatchery rainbow trout were collected and ranged in length from 250 mm to 350 mm.

Wild Rainbow (redband) Trout

Four wild rainbow were collected and ranged in length from 321 mm to 419 mm. Although the upper Boise River watershed provides a source of wild rainbow trout to Lucky Peak, our netting suggests the wild fish constitute a small portion of the rainbow trout population in Lucky Peak. Past fisheries surveys have also caught few wild rainbow. Netting conducted in 1994 and 1997 resulted in the capture of two wild rainbow each (Allen et al. 1995; Allen et al. 2000).

Fall Chinook Salmon

Fall chinook were first planted in Lucky Peak in 1984. Between 1984 and 1995 there were no documented recaptures from reservoir netting or angler reports. Beginning in 1995, annual fall chinook fingerling plants were initiated. Netting conducted in 1998 resulted in the capture of two chinook, ranging in length from 294 mm to 436 mm. The mean length for chinook captured in 1996, 1997, and 1998, were 281 mm, 334 mm, and 365 mm, respectively (Allen et al. 1997, Allen et al. 1998a). Anglers reported harvesting chinook relatively frequently in 1998, with some reports of fish that approached 3 kg. Based on releases of approximately 6,300 fingerling chinook in 1995 and 1996, Lucky Peak appears capable of producing harvestable fall chinook from fingerling plants. The availability of surplus chinook in 1998 resulted in the stocking of 17,141 fingerlings in June. Lucky Peak Reservoir historical fall chinook stocking information can be found in table 3.

Smallmouth Bass

A total of nine smallmouth bass were captured. The bass ranged in length from 235 mm to 240 mm with a mean length of 309 mm. The CPUE by number for gillnetting was 4.5. Sampling conducted in 1997 captured 24 smallmouth while electrofishing and three while gillnetting (Allen et al. 2000). The mean length of smallmouth collected in 1997 by electrofishing and gillnetting was 238 mm and 317 mm, respectively.

Yellow Perch

A total of seventeen yellow perch were captured. The perch ranged in length from 135 mm to 272 mm.

Deadwood Reservoir Bull Trout Investigations

METHODS

Tributary Weirs

Wild Buck and Basin creeks had picket type weirs constructed and monitored from May 11 to May 16,1998 and from May 19 to May 22, 1998. The weirs were located above the reservoir pool and near bridges for forest road 555. The weirs were constructed to a typical Department design of steel frame and vertical pickets. The steel frames were modified from the design used by Elle et al. (1994) in that the frame was shortened to 5 ft to allow better backcountry transport. The pickets were of ½ inch electrical conduit of various lengths. Two trap-boxes with 200 mm diameter flexible black drainage pipe were located so that one box trapped upstream moving fish and the other trapped downstream migrants. The trap measured 1.0 m by 0.5 m by 0.3 m and was constructed of a pine frame covered with metal hardware cloth with 1.0 cm square mesh. The weirs were checked at least twice daily, cleaned of debris and adjusted for the volume of stream flow. The trap-boxes were monitored twice daily and all fish were identified to species, measured for total length and released.

Deadwood Reservoir Fish Capture

Only trap nets were utilized for reservoir sampling in 1998. The trap nets were a standard Department design as previously described in this report. Trap nets were set in the late PM and checked and moved the following morning. All fish species were identified, measured for total length and released. Any bull trout captured were weighed a fin clip taken. Larger fish were saved to have radio transmitters implanted. Telemetry transmitters were surgically implanted as in Flatter 1997.

RESULTS

Tributary Weirs

Only one fish was captured during the operation of the two weirs in May 1998. A westslope cutthroat trout *Oncorhynchus clarkii clarkii* was captured on May 13, 1998 and was 115 mm in TL. No other fish were observed either above or below the weirs. The weirs did not get breached or overflowed during the sampling period.

The weirs were installed just after the peak of snowpack runoff. We expected to encounter spawning cutthroat and rainbow trout utilizing the two tributaries. The reason for the weir placement was a suspicion that bull trout would follow spawning migration trout to prey on fresh spawn. I suspect that we were too late and any trout had already spawned and returned to the lake. We had used all possible means to enter the drainage as soon as possible given the existing snowpack.

Reservoir Sampling

Deadwood Reservoir was sampled with trap nets from May 12 to May 22, 1998. A total of 41 trap net nights of effort were accomplished by utilizing multiple trap nets each night. Two bull trout were captured with a length and weight of 235 mm, 100 g and 370 mm, 535 g. Capture of other fish species was extremely low. Likely the low catch rates were a result of cold water temperatures.

The larger of the captured bull trout was implanted with an internal radio transmitter to allow for radio tracking. Since we had captured so few bull trout and implanted only one transmitter, no telemetry work was done to locate the one radio later in the year.

Recommendations

1. Increase education efforts to help anglers identify bull trout.

2. Cooperatively conduct a creel survey on Deadwood Reservoir with the Lowman District Ranger District, Boise National Forest when funding is available.

Bull Trout Lake Area Creel Surveys

INTRODUCTION

During the 1998 summer fishing season a creel survey was conducted by the camp hosts operating the Bull Trout Lake Campgrounds. With the assistance of the USFS, Boise National Forest, Lowman Ranger District staff, the stocking of these lakes was evaluated to determine if the return rates of stocked rainbow trout were acceptable. The purpose of the creel survey was to document the return to the angler of stocked rainbow trout in four of the area's lakes. A goal of a 40% return rate of stocked rainbow trout was created to decide if the program was a success. Bull Trout Lake had been stocked by Department in the past but was discontinued due to perceived low return rates of stocked trout. Martin Lake has been stocked for many years with rainbow trout and return rates have been perceived to be acceptable. The Salmon Region of Department has recently added three smaller area ponds on the road into Bull Trout Lake to the stocking schedule.

METHODS

The creel survey was a stratified two-stage probability design and was scheduled to run from July 1 to September 15, 1998. Eight days per month were selected for sampling, which included 4 weekdays and 4 weekend days. The probabilities between the two strata were set equal. The secondary sampling unit chosen was the day length, divided into three units of equal length and with equal probabilities. Each lake was treated as an independent unit and not subdivided into smaller sub-units because the small lake size allowed complete counts. A sampling schedule was randomly selected and provided to the Lowman Ranger District staff. The instantaneous counts were to be taken at each lake followed by individual angler interviews

and then the creel clerk would proceed to the next lake. The camp host, employed by a contractor to the USFS, would do the actual counts and interviews supervised by the forest district staff. The creel clerks would interview anglers to quantify the hours fished by each angler, method of fishing, either bank, boat or float tube, and the anglers catch by species. The collected data were entered into the Department's Creel Census System (McArthur 1992) and estimates of effort and harvest for each lake were created. Future stocking recommendations will consider the estimated percent return to the angler of the stocked rainbow trout, using a 40% return percentage as a goal for each lake. Lakes with less than 40% return of rainbow trout will not be stocked in the future.

RESULTS

Bull Trout Lake

Anglers expended an estimated 3,020 hours of fishing effort on Bull Trout Lake in the summer season of 1998 (Table 4). The majority of hours fished were from the bank and secondly from boats (Table 4). Anglers harvested an estimated 1,684 stocked rainbow trout (Table 5) which equaled 49.6% of the 3,390 rainbow trout stocked. An additional 3,846 brook trout were also harvested from the lake. The average catch rate was estimated at 0.32 rainbow trout per hour and 0.75 brook trout per hour (Table 5). The creel clerks recorded only numbers of fish harvested (kept) so catch rates do not include released fish, thus the catch rates reflect an actual harvest rate.

Martin Lake

Anglers on Martin Lake fished an estimated 1,276 hours from the shore (Table 4). This estimated effort was probably reduced because local campground construction prevented vehicle access to the small lake. The estimated harvest of rainbow trout was quite high at an estimated 1,997 $\pm$ 859 fish (Table 5). A total of 2,290 rainbow trout were stocked which resulted in an 87.2% return of the stocked trout. The catch rate for rainbow trout was estimated at 1.1/hour (Table 5). Some rainbow trout may have carried over from the previous summer and contributed to these returns. Brook trout also contributed an estimated 1,314 fish to the anglers.

Pond # 1

This small lake is the first lake on the left of the road into Bull Trout Lake Campground and is sometimes referred to as Little Bull Trout Lake. A total effort of 1,226 hours was estimated (Table 4) for this little lake in 1998. Harvest of rainbow trout was estimated at 866 and estimated harvest of brook trout was 724 (Table 5). The estimated harvest of rainbow trout exceeded the 450 rainbow trout stocked by almost twice. The low number of anglers interviewed during the season mostly explains this discrepancy. Some trout could have survived from the previous year and contributed to the inflated estimate also.

Pond # 2

Pond # 2 in this study is the second pond along the road and lies on the right-hand side of the road. An estimated 235 hours of fishing effort was calculated for this pond (Table 4). No anglers were interviewed so no estimate of harvest could be calculated. A stocking of 450

rainbow trout was done in 1998. Either the anglers did not know this pond was stocked or it was not accepted as a good place to fish.

Pond # 3

This is the third pond in from the road and nearest to Bull Trout Lake. It was not included in this study because it was wrongly assumed by this author not to be stocked. In fact this pond received 450 rainbow trout. No estimates of pressure or harvest can be made.

RECOMMENDATIONS

1. Continue to stock Bull Trout Lake and increase annual stocking of rainbow trout to 4,500.

2. Continue to stock Martin Lake at 2,750 rainbow trout.

3. Recommend to Salmon Region they continue to stock pond # 1 and increase numbers of trout, if possible.

4. Recommend to Salmon Region that they discontinue stocking the other two ponds in the area.

5. For future creel surveys conducted invest more time into training the volunteer creel clerks. More angler interviews would have allowed more precise estimates of harvest. Also the creel clerks did not record any released fish during the survey. Again this was likely due to inadequate training of the creel clerks by this author.

Table 1. Hatchery releases of Lahontan cutthroat trout into Lake Lowell during 1995 to 1998.

Lahontan Cutthroat Releases		
Date	Number	Size
May 1995	25,000	Fry
Sept. 1995	7,500	Fingerling
Sept. 1996	42,500	Fingerling
Sept. 1997	22,700	Fingerling
July 1998	84,000	Fry
Sept. 1998	12,900	Fingerling

Table 2. Angler return rate of hatchery rainbow trout marked with jaw tags in Mann Creek Reservoir during 1998.

Date released	Number released	Number returned	Percentage
March 23	200	16	8.0
April 22	200	29	14.5
May 20	100	15	15.0
September 29	200	32	16.0
October 15	200	24	12.0
Total	900	116	12.9

Table 3. Hatchery releases of fall chinook salmon into Lucky Peak during 1984 to 1998

Fall Chinook Releases		
Date	Number	Size
October 1984	2,034	Fingerling
July 1995	5,280	Fingerling
June 1996	7,250	Fingerling
June 1998	17,141	Fingerling

Table 4. Hours of fishing pressure estimated from a roving creel survey conducted July to mid-September 1998 on Bull Trout Lake and Martin Lake and two smaller ponds stocked with catchable rainbow trout.

Water	Hours of Fishing Pressure from Bank Anglers (±95% C.I.)	Hours of Fishing Pressure from Boat Anglers (±95% C.I.)	Hours of Fishing Pressure from Float Tube Anglers (±95% C.I.)	Total Hours of Fishing Pressure for Season (±95% C.I.)
Bull Trout Lake	1430 (1413)	1032 (692)	558 (445)	3020 (1635)
Martin Lake	1276 (680)	0	0	1276 (680)
Pond # 1	860 (924)	366 (436)	0	1226 (1022)
Pond # 2	235 (274)	0	0	235 (274)

Table 5. Harvest and catch rates estimated from a roving creel survey conducted July to mid September 1998 on Bull Trout Lake and Martin Lake and two smaller ponds stocked with catchable rainbow trout.

Water	Rainbow Trout Harvest (+95%C.I.)	Brook Trout Harvest (+95%C.I.)	Season Trout Harvest (+95%C.I.)	Rainbow Trout Catch Rate	Brook Trout Catch Rate	Seasonal Average Catch Rate
Bull Trout Lake	1684 (1757)	3861 (2694)	5546 (3683)	0.32	0.75	1.07

1998 ANNUAL PERFORMANCE REPORT

State of: Idaho | Program: Fisheries Management F-71-R-23

Project I: Surveys and Inventories | Subproject I-D: Southwest Region

Job No.: c | Title: Rivers and Streams Investigations

Contract Period: July 1, 1998 to June 30, 1999

ABSTRACT

A team of biologists attempted to develop a method to identify adult bull trout *Salvelinus confluentus* in the lower Deadwood River below Deadwood Dam. Four biologists floated the roadless section of river below the dam in inflatable kayaks to approximately 5 km from the river mouth. The pool habitat areas were sampled by snorkeling. The sampling crew did not locate any bull trout. Suitable snorkel sites were infrequent due to the high river gradient and flows.

A survey was conducted on the upper Deadwood River from Deer Creek to Deadwood Reservoir to locate any hatchery fall chinook *Oncorhynchus tshawytscha* redds. A total of 12 chinook redds were identified on October 6, 1998

The Payette River was sampled with boat mounted electrofishing gear at eight stations from near Black Canyon Dam to the confluence with the Snake River. The data collected was used to define fish species distribution and their relative abundance from the Dam to the mouth. Data collected was compared to data from 1977. Rainbow trout *O. mykiss* were not collected at any site. Mountain whitefish *Prosopium williamsoni* were present in all river reaches. Sculpin, *Cottus spp.* were only captured between Black Canyon Dam and the town of Emmett, Idaho.

Dale B. Allen
Regional Fishery Manager

DEADWOOD RIVER

Introduction

Deadwood Reservoir investigations were continued in 1998 by the Southwest Region Idaho Department of Fish and Game (Department) to further document the population status of bull trout *Salvelinus confluentus* for the U.S. Department of Interior, Bureau of Reclamation, Pacific Northwest Region (BOR). Bull trout are found in the Deadwood drainage in tributaries to the reservoir, the Deadwood River above the reservoir and the reservoir proper (Allen 1998). The Deadwood River below Deadwood Dam has not been surveyed for the presence of bull trout. We attempted a reconnaissance level survey of the lower river to locate any bull tout that might be in the mainstem river corridor.

Methods

The lower Deadwood River was investigated by biologists floating the river in inflatable kayaks and snorkeling the large pools and tributary mouths. The lower Deadwood River is a roadless area for approximately 40 km before a Forest Service road crosses the river. Four biologists began kayaking the Deadwood River below the dam on August 10 and vacated the river downstream on August 13, 1998. The snorkelers were to identify and estimate numbers of any bull trout observed.

Results

No bull trout were observed on the trip. Snorkel sites were rather rare at the flows (600 cfs) experienced on the trip. Typically we encountered very small pools that contained large amounts of dissolved gas bubbles which limited snorkeling observations. The river was generally a high gradient run riffle complex with little pool habitat available. The lower ends of tributary streams were surveyed. No bull trout were observed in the tributaries. Generally we observed few fish in the river. Pool species observed were mountain whitefish *Prosopium williamsoni* and redband trout *Oncorhynchus mykiss gairdneri*. Generally the fish numbers were low; no density estimates were made. Water temperature through most of the float trip was 4° C.

UPPER DEADWOOD RIVER REDD SURVEY

Methods

The Deadwood River from Deer Creek mouth to the reservoir was surveyed for the presence of fall chinook *O. tshawytscha* redds on October 10, 1998. The survey was completed by two

biologists walking the bank downstream and identifying possible fall chinook redds, and identifying any live fish and or carcasses.

Results

Twelve redds were identified; ten adult fall chinook were observed, and two fall chinook carcasses were located.

Recommendation

1. Annually conduct redd surveys in the area above Deadwood Reservoir during mid-October.

PAYETTE RIVER - BLACK CANYON DAM TO MOUTH

Introduction

During late 1996 the Southwest Region fish management group was asked by the Lower Payette River Watershed Advisory Group to develop a fishery monitoring plan for the lower Payette River. The last substantive survey of this reach was done by Reid (1975). The objective of this project was to describe the fish community in the Payette River between Black Canyon Dam and the confluence with the Snake River.

Methods

Eight access points were selected because of the ability to launch and operate a small electrofishing jetboat. The approximate location of each site was at rivermile (RM): 1,4, 15, 18, 25, 30, 33, 36. Fish collection efforts were done twice for each sample site in July and then repeated in October of 1997. Electrofishing was conducted for 1800 seconds of energized field time on each bank of the river. Electrofishing was generally done floating downstream with the current. A boat operator and one netter accomplished the fish collection.

Electrofishing gear was powered by a 5000 watt generator with 230v output. The output voltage was generally set to run on straight DC. Pulsed DC was utilized when straight DC was deemed ineffective. Voltages ranged from 300 to 425v at 3 to 8 amp during sampling.

During electrofishing operations attempts were made to collect all fish immobilized by the gear. Netted fish were placed into a live car and held until the sample section was completed. Fish collected were identified as to species, measured to the nearest cm, and weighed to the nearest g. Processed fish were returned to the river. Data was entered into a regional fishery database and

summarized into length frequency by species. Fishery indices were compared to 1974 data reported in Reid (1975).

Results

Species Composition

The composition of fish species captured in 1997 was similar to the species documented by Reid (1975). The most numerous species were mountain whitefish *Prosopium williamsoni,* chiselmouth Acrocheilus *alutaceus*, redside shiner *Richardsonius balteatus,* and largescale sucker *Catostomus macrocheilus*. Some seasonal differences in ranking of abundance between species were seen (Table 1) and Reid (1975). Reid (1975) documented brown trout *Salmo trutta*, black crappie *Pomoxis nigromaculatus*, warmouth *Lepomus gulosus,* and white catfish *Ictalurus catus* which were not captured in this study but these species were also rare in Reid's study.

Some caution must be taken on interpreting the species composition of both studies because only electrofishing equipment was employed to capture fish. Also the type of equipment was different in the two studies, Reid used a throw probe anode where in 1997 the anodes were boom mounted to a jet boat. Secondly, habitats sampled probably differed between studies which could influence species capture rates. It would have been wise to incorporate some type of seining methods to capture smaller fish species. Sample site descriptions for the eight sample sites, species composition and length frequencies of captured fish are provided in Appendix A.

Species Distribution

Distribution of captured fishes is presented by sample site and month in Table 2. We could not compare against Reid (1975) because previous data was not presented by sample sites. Rainbow trout *Oncorhynchus mykiss*, were only captured in the uppermost reach directly below Black Canyon Dam. These rainbow trout were hatchery fish that had been stocked near this site in the fall. Sculpin species *Cottus* spp. also were limited to the upper sample reaches above Emmett. Mountain whitefish were distributed from the mouth to the dam. Most of the nongame fishes were also widely distributed (Table 2). Smallmouth bass *Micropterus dolomieui* were also captured at most sites.

Conclusions

The majority of gamefish in these reaches of the lower Payette River that a sportsman would be interested in pursuing were non-native warmwater species. Mountain whitefish were the only coldwater species represented throughout the whole study area. We do not know if reproduction of mountain whitefish is supported throughout the whole study area. No brown trout were captured even after stocking for over five years below the Dam. Likely this introduction effort failed and has been discontinued. We suspect that warm water temperatures in certain reaches directly affect the distribution of fishes in these reaches of the Payette River. A valuable additional dataset need is reach-wide water temperature data.

Table 1. Comparison of species composition from boat electrofishing sampling on the Payette River from Black Canyon Dam to mouth, July versus October 1997.

July 1997 Fish species	Percent	October 1997 fish species	Percent
		Brown bullhead *Ameirus nebulosus*	0.5

1998 ANNUAL PERFORMANCE REPORT

State of: Idaho

Program: Fisheries Management F-71-R-23

Project I: Surveys and Inventories

Subproject I-D: Southwest Region

Job No.: d

Title: Salmon and Steelhead Investigations

Contract Period: July 1, 1998 to June 30, 1999

ABSTRACT

Salmon spawning ground surveys were conducted in Bear Valley, Elk, and Sulphur Creek trend areas on August 24-30, 1998. Salmon redds numbered 102, 105, and 47 in Bear Valley, Elk, and Sulphur Creek trend areas, respectively.

Additional data on Southwest Region salmon and steelhead investigations are incorporated in a separate, statewide Salmon and Steelhead Investigations report.

Author:

Dale B. Allen
Regional Fishery Manager

METHODS

Redd Counts

Redds were enumerated according criteria described in the draft Idaho Redd Counting Manual. Carcasses encountered were identified as to sex (F-female, M-male) and measured (fork length) where possible. When possible, live fish observed were visually classified as to sex and ocean age (jacks, II, or III, IV).

RESULTS

Redd Counts

Salmon redds were counted in trend areas in Bear Valley, Elk, and Sulphur creeks on August 24-30, 1998. Redds counted, dates of counts, live fish observed, and carcasses encountered by area are reported in Table 1.

Table 1. Redd counts, live fish and carcasses identified in Bear Valley, Elk, and Sulphur Creeks from August 24 – 30, 1998.

1998 ANNUAL PERFORMANCE REPORT

State of: Idaho Program: Fisheries Management F-71-R-23

Project II: Technical Guidance Subproject II-D: Southwest Region

Contract Period: July 1, 1998 to June 30, 1999

ABSTRACT

Regional fishery personnel continue to respond to a large number of public requests for fishing information. Biweekly ASK FISH reports were prepared and forwarded to vendor for distribution. Regional fishery staff consulted with the Environmental Staff Biologist for requests on fish population status and concerns on a multitude of projects in the Southwest Region. Numerous requests for fish stocking advice and/or rates were received from local Treasure Valley residents.

Regional staff completed three pond construction projects within the Southwest Region in 1998. The Lowman Nature Fishing Ponds located near the Ten Mile Creek Bridge in upper Lowman were completed in cooperation with the Boise National Forest, Lowman Ranger District. The Idaho City Interpretive Center Pond was expanded with excavators, a fishing pier and aeration system were also added in cooperation with the City of Idaho City and the Boise Basin Interpretive Association. Ed's Pond was excavated from a shallow pit on Gem Island on lands owned by the Department and Gem County. Gem County contracted the excavation work and also used volunteer labor to construct the pond.

1998 ANNUAL PERFORMANCE REPORT

State of: Idaho Program: Fisheries Management F-71-R-23

Project IV: Habitat Management Subproject III-D: Southwest Region

Contract Period: July 1, 1998 to June 30, 1999

ABSTRACT

Habitat concerns were addressed in multiple comments to public agencies and private parties through reviews of projects that the Southwest Region addressed in 1998.

Regional fishery staff conducted no specific habitat projects during this report period.
