## OVERVIEW

This report contains summaries of Lower Snake River Compensation Plan and Idaho Power Company hatchery Chinook Salmon programs at both the calendar (2019) and brood year (2013) level. The report contains two chapters that describe monitoring and evaluation of the programs during 2019 (Chapter 1) and the performance of brood year 2013 cohorts both in the hatchery and as returning adults from 2016-2018 (Chapter 2).

#### Abstract

This report details components of spring-, summer-, and fall-Chinook Salmon monitoring, evaluation, and management activities during calendar year 2019 for hatchery mitigation programs funded by the Lower Snake River Compensation Plan (LSRCP) and Idaho Power Company (IPC). Information is reported for Chinook Salmon from five different hatcheries operated by the Idaho Department of Fish and Game (IDFG) including three (Clearwater, McCall, and Sawtooth hatcheries) owned by LSRCP and two (Pahsimeroi and Rapid River hatcheries) owned by IPC. Data reported includes juvenile production and releases, outmigration survival, adult returns, contribution to fisheries, and returns to hatchery traps.

Hatcheries operated by IDFG released 9,809,039 Chinook Salmon smolts, which did not meet the statewide release goal of $10,750,000$. Survival of juvenile release groups from release to Lower Granite Dam ranged from $13 \%$ to $68 \%$ with a weighted average of $52 \%$, which was $11 \%$ lower than the previous ten-year weighted average of 63\%.

The preseason forecasts for adult Chinook Salmon (one-ocean jacks excluded) destined for hatchery facilities operated by IDFG were 30,343 to the Columbia River mouth, 27,558 to Bonneville Dam, and 19,787 to Lower Granite Dam. Based on post-season analysis, the estimated adult escapement was 23,935 Chinook Salmon at the mouth of the Columbia River, 23,194 at Bonneville Dam, and 15,319 at Lower Granite Dam.

We estimated hatchery-origin Chinook Salmon escapement above Lower Granite Dam by age (including jacks) and release-site using parentage based tagging (PBT) and the SCOBI methodology. We estimated 24,434 hatchery origin Chinook Salmon from brood years 2014-2016 migrated upstream of Lower Granite Dam in 2019. PIT tags represented the PBT estimates at a rate of $69 \%$ across all PIT-tagged release groups and age classes. We also estimated fallback with reascension and night passage rates for adults and jacks to determine potential bias in the reported window counts. Our results suggest that the adult window count was overestimated by 1,369 Chinook Salmon and the jack window count was overestimated by 440 Chinook Salmon in 2019.

Sport fisheries in Idaho were conducted for spring/summer Chinook Salmon in the Snake, Clearwater, and Salmon rivers and fall Chinook Salmon in the Snake and Clearwater rivers. During spring/summer Chinook Salmon fisheries, we estimated anglers caught 739 Chinook Salmon, harvested 696 Chinook Salmon, and expended 14,953 hours of fishing effort resulting in catch rates of 20 hours per fish caught and 21 hours per fish kept in 2019. During fall Chinook Salmon fisheries, we estimated anglers caught 1,603 Chinook Salmon, harvested 525 Chinook Salmon, and expended 55,060 hours of fishing effort resulting in catch rates of 34 hours per fish caught and 51 hours per fish kept.

Based on escapement estimates at Lower Granite Dam, none of the LSRCP-funded facilities operated by IDFG achieved the adult mitigation goals for spring/summer Chinook Salmon. The number (and percent) of the project area escapement goal achieved by Clearwater, McCall, and Sawtooth fish hatcheries was 5,928 (50\%), 3,136 (39\%), and 2,983 (15\%).

## INTRODUCTION

This report details various components of hatchery-origin spring, summer, and fall Chinook Salmon monitoring, evaluation, and management for calendar year 2019. Information is reported for Chinook Salmon from five different hatcheries operated by the Idaho Department of Fish and Game (IDFG). These facilities include three hatcheries funded by the Lower Snake River Compensation Plan (LSRCP) and two hatcheries funded by the Idaho Power Company (IPC).

The LSRCP hatchery program specified the use of fish hatcheries to compensate for the salmon and steelhead mortality caused by the construction and operation of the four lower Snake River dams. The strategy was to produce and release enough juvenile anadromous salmonids to meet the program's adult return goals. The adult return goals were based on the estimated adult and juvenile fish losses that would result from operation of the four dams. Original loss estimates for spring- and summer-run Chinook Salmon attributable to the four lower Snake River dams were derived by applying a $15 \%$ smolt mortality rate at each of the four dams (a total estimated loss of 48\%) (U.S. Army Engineer District 1975). That expected loss was multiplied by the estimated average return of spring/summer Chinook Salmon adults $(122,200)$ to the Snake River from 19591961 (pre-dam construction) to estimate an annual average loss of 58,677 spring and summer Chinook Salmon. The loss estimate became the annual escapement goal of 58,677 spring- and summer-run (50,677 spring-run and 8,000 summer-run) Chinook Salmon to Lower Granite Dam (LGD [i.e. above the project area] [Herrig 1990]). Of this mitigation goal, 39,360 adult returns are allocated to hatchery facilities operated by the Idaho Department of Fish and Game (IDFG). Additionally, an assumed 4:1 ratio of catch below LGD to above LGD was used to estimate an additional loss of 234,777 in the coastwide commercial, tribal, and recreational fisheries downstream of the project area. These combined catch and escapement estimates resulted in total mitigation of 293,454 adults produced annually for the entire LSRCP program (196,800 for facilities operated by IDFG). It was anticipated that the majority of the harvest mitigation benefits would be distributed downstream of the project area. However, less than expected returns of hatchery fish produced within the program and the depressed status of natural-origin fish influenced Columbia River fisheries management programs. The anticipated 4:1 distribution of benefits downstream: upstream of the project area has not been realized. Based on recent natural-origin and hatchery-origin return abundances and the current ESA listing status of Snake River stocks, it is likely that the current distribution of harvest benefits will continue into the foreseeable future (Table 1).

Table 1. Adult spring- and summer-run Chinook Salmon mitigation for LSRCP-funded hatcheries located in Idaho and operated by IDFG. Return goals listed for satellite facilities are a subset of the overall hatchery return (in bold font).

|  |  |  | LSRCP Adult return mitigation |  |  |

a Release sites have changed since the inception of the Clearwater Fish Hatchery mitigation program.

Idaho Power Company (IPC) constructed Rapid River and Pahsimeroi fish hatcheries to meet a Federal Energy Regulatory Commission (FERC) mandate to mitigate for the ongoing operation of the Hells Canyon Dam Complex (Brownlee, Oxbow, and Hells Canyon Dams). While IPC owns and maintains Rapid River and Pahsimeroi Fish Hatcheries, IDFG staffs and operates the hatcheries. Mitigation goals established through the Hells Canyon Settlement Agreement specify juvenile production targets of three million spring Chinook Salmon smolts at the Rapid River Fish Hatchery and one million summer Chinook Salmon smolts at the Pahsimeroi Fish Hatchery (Table 2). A complete description of mitigation goals and hatchery programs can be found in Sullivan et al. (2018).

Table 2. Chinook Salmon mitigation goals for IPC-funded hatcheries located in Idaho and operated by IDFG.

| Hatchery | First year of operation | Run type | Smolt release goal |
| :---: | :---: | :---: | :---: |
| Rapid River | 1965 | Spring | $3,000,000$ |
| Pahsimeroi | $1981^{\mathrm{a}}$ | Summer | $1,000,000$ |
| Total |  |  | $4,000,000$ |

a The Pahsimeroi Fish Hatchery was constructed in 1967 but production of Chinook Salmon did not begin until 1981 as a result of the Hells Canyon Settlement Agreement.

Between 2017 and 2020, the Marine Fisheries Advisory Council convened the Columbia Basin Partnership Task Force (Partnership). The Partnership, which included members representing public utilities, state governments, commercial fishers, non-governmental organizations, water users, and tribal governments, established qualitative and quantitative goals for Chinook Salmon, steelhead, Sockeye Salmon, and Coho Salmon in the Columbia basin. Setting these goals provided stakeholders in the Columbia River basin with a common currency to use during discussions regarding the status of anadromous fish. In the Partnership framework, hatchery and wild/natural origin fish were considered separately for both qualitative and quantitative goals. Qualitative goals for hatchery fish included supplementation, mitigation, and conservation, while quantitative goals were set using historical escapement and harvest estimates. Based on this process, the quantitative escapement goal for adult spring/ summer run Chinook Salmon above Lower Granite Dam was set at 90,000 hatchery fish and 127,000
wild/natural fish (NOAA 2019). The IDFG Commission formally adopted these goals by including them in the latest Idaho Fisheries Management Plan (IDFG 2019).

Figure 1. State-, federally-, and tribally-operated anpadromous fish hatcheries located in the Clearwater, Salmon, and mid-Snake river basins along with associated satellite facilities and juvenile release locations.

## JUVENILE PRODUCTION AND RELEASE

Brood year 2017 juvenile Chinook Salmon were released between mid-March and late April of 2019. Release goals were not met at Sawtooth, Clearwater, or Pahsimeroi hatcheries (Table 3). The majority of juvenile Chinook Salmon releases from IDFG hatcheries do not change from one year to the next, however, there were three deviations from normal operations in 2019 that bear specific descriptions here. First, IDFG is in the midst of an evaluation to determine if juvenile and adult survival rates for Chinook Salmon reared in baffled raceways is different than Chinook Salmon reared in standard raceways for the NF Clearwater release group. Second, a paired rearing and release feasibility trial was undertaken at the request of the ShoshoneBannock Tribes using Chinook Salmon destined for the Yankee Fork Salmon River. Approximately $50 \%$ of the smolt release was reared at Sawtooth Fish Hatchery and $50 \%$ of the smolt release was reared at Springfield Fish Hatchery in southeastern Idaho to determine if the water source in southeastern Idaho produced smolts that survived to LGD at a similar rate as smolts reared on water from the Upper Salmon River. Finally, the Red River release group was split into two separate releases; one group was released at Red River and one was released in the NF Clearwater River because spring storms caused record high flows and debris flows in the South Fork Clearwater River.

## Juvenile Survival

Juvenile survival rates of PIT-tagged Chinook Salmon are estimated from release site to LGD using the SURPH (Lady et al. 2001) and PitPro programs (Westhagen and Skalski 2009) developed in the Columbia Basin Research laboratory in the School of Aquatic and Fishery Sciences at the University of Washington. Chinook Salmon survival rates to LGD ranged from 13\% (Yankee Fork release group reared at Springfield Fish Hatchery) to 69\% (NF Clearwater release group). In two of the three evaluations outlined previously, survivals to LGD were different between release groups. Survival rates to LGD were not different for Chinook Salmon reared in baffled raceways compared to standard raceways. However, survival rates to LGD for Chinook Salmon reared at Sawtooth Fish Hatchery and released into the Yankee Fork Salmon River were higher than Chinook Salmon reared at Springfield Fish Hatchery and released into the Yankee Fork Salmon River. Chinook Salmon released into Red River survived at a lower rate than

Chinook Salmon released into the NF Clearwater River (Table 4). The yearly-weighted average for all release groups combined was $52 \%$ which was lower than the previous nine-year weighted average of 63\% (Table 5).

## ADULT RETURNS

Chinook Salmon returns to the Columbia River and the Snake River provide sport, commercial, and tribal fishing opportunities. Fisheries in the lower Columbia River are set and managed based on forecasted abundance estimates followed by in-season abundance estimates that are derived using dam counts and historic run timing. Managers use these abundance estimates coupled with harvest estimates to decide which fisheries will open and to determine how long fisheries will remain open. In the Snake River, managers estimate escapement using PIT tags and genetic methods. In this section we report pre-season forecasts, in-season abundance estimates, harvest estimates, and end of season abundance estimates used by managers in the Columbia and Snake rivers. We focus specifically on estimates for Chinook Salmon released from hatcheries operated by IDFG in our reporting. Though Chinook Salmon bound for Idaho are encountered in tribal fisheries, differences in data availability and monitoring methods preclude their inclusion in this calendar year report. Fall Chinook Salmon are not included in the majority of adult return summaries because of differences in data reporting responsibilities. A cooperative group of representatives from the Nez Perce Tribe (NPT), the Washington Department of Fish and Wildlife (WDFW), LSRCP, and IPC complete a run reconstruction each year to estimate Fall Chinook Salmon escapement above LGD, and those estimates are available in Young et al. (2019). We do report sport harvest of fall Chinook Salmon in the Sport Fisheries in Idaho section below.

## Forecasted Adult Returns

Forecasts of adult returns for Snake River stocks are generated by an interagency technical workgroup including IDFG, NPT, ODFW, and WDFW using sibling regressions. A regression of historic jack returns vs. two-ocean returns, from the same cohort, is used to forecast a hatchery's two-ocean return. The same methodology is used to forecast three-ocean returns from the previous year's two-ocean return. The regressions use hatchery-specific run reconstructions, by age, at the Columbia River mouth. The forecasted total adult return to the Columbia River mouth, for each hatchery, is the sum of the forecasted two- and three-ocean returns. Forecasts are not developed for one-ocean jacks. Release group-specific conversion rates based on historic (i.e. running 5-year average) inter-dam PIT tag conversions are applied to each hatchery-specific forecast to the Columbia River mouth to generate release group-specific forecasts to LGD (Table 6).

Table 6. Summary of forecasted adult (two- and three-ocean) spring/summer Chinook Salmon returns in 2019 by hatchery and release group to the Columbia River mouth, Bonneville Dam, and Lower Granite Dam for hatchery facilities operated by IDFG.

## Sport and Commercial Harvest in the Lower Columbia River

Aggregate harvest estimates in the sport and commercial fisheries in the lower Columbia River are based on spatially and temporally stratified creel estimates which are decomposed into release group and age class specific harvest estimates using CWT collected during the creel surveys. Only spring period sport and winter/spring Select Area Fishery Enhancement (SAFE) area fisheries harvest estimates are reported here (Table 7), because these were the only fisheries open for spring and summer Chinook Salmon.

Table 7. Season and aggregate harvest estimates for the spring sport and spring SAFE fisheries in the 2019 lower Columbia River.

| Management Period | Fishery | Total harvest |
| :--- | :--- | ---: |
| Spring | Sport | 1,709 |
| Spring | SAFE | 8,744 |

Chinook Salmon from IDFG hatcheries contributed to the lower Columbia River sport and the SAFE fisheries in 2019. On the aggregate level in the lower Columbia River sport fishery, salmon released from IDFG hatcheries accounted for $42 \%$ of the total spring management period
harvest. Releases from Rapid River hatchery accounted for 66\% of the IDFG hatchery attributed harvest in the spring management period while releases from Clearwater Hatchery accounted for the remainder of the harvest attributed to IDFG hatchery releases. Releases from McCall, Pahsimeroi, and Sawtooth fish hatcheries did not contribute to harvest in the spring or summer management period in 2019. All harvest in the lower Columbia River sport fishery was attributed to returns from 2- and 3-ocean adults from brood year 2014 and brood year 2015 (Table 8).

## Adult Return Estimates to Bonneville and Lower Granite Dams Based on PIT Tag Detections

Preseason forecasts allow managers to plan for Chinook Salmon fisheries before the season begins; however, in-season estimates of stock-specific abundances are needed to set harvest limits and seasons in real time for fisheries in Idaho. These estimates are generated using adult Chinook Salmon PIT tag detections in the Columbia and Snake rivers. The majority of the release groups of Chinook Salmon returning to Idaho in 2019 were representatively tagged as juveniles prior to release. Adult Chinook Salmon PIT tag detections at Bonneville, McNary, Ice Harbor, and Lower Granite dams were expanded using equation 1 to estimate adult returns and harvest shares in-season. Rapid River tags were used as a surrogate to estimate returns for the Hells Canyon, and Little Salmon River release groups, and Red River tags were used as a surrogate to estimate returns for the Mill Creek release group because the Hells Canyon, Little Salmon River, and Mill Creek release groups were not PIT tagged. Estimates of adult Chinook Salmon at Bonneville Dam and LGD are provided in Tables 9 and 10.

Equation 1. Adult Chinook Salmon PIT tag expansion calculation for monitor mode PIT tags detected at Columbia and Snake River Dams.

PIT Expansion $=\frac{\# \text { of juvenile Chinook released }-\# \text { of default mode PIT tags }}{\# \text { of monitor mode PIT tags }}$
Table 9. Estimated escapement of hatchery-origin spring/summer Chinook Salmon to Bonneville Dam in return year 2019. Estimates are based on expanded PIT tag detections.

## Adult Return Estimates to the Columbia River Mouth, Bonneville Dam, and Lower Granite Dam Based on Parentage Based Tagging

Since return year 2012, IDFG has used Parentage Based Tagging (PBT) to estimate the stock- and age-specific returns of hatchery-origin Chinook Salmon to LGD. Estimates are derived using parentage analysis from tissue samples collected at the LGD fish trap, to partition out the LGD window count. The genetic and analytical methods used to decompose Chinook Salmon escapement over LGD can be found in Steele et al. (2018) and Camacho et al. (2019). In 2019, we used these decomposed escapement estimates for hatchery origin Chinook Salmon at LGD and age-specific PIT tag conversion rates to calculate PBT-based estimates of escapement over Bonneville dam.

Comparisons of release site- and aggregate-level PBT escapement estimates to PIT tag estimates at LGD in previous years suggest that PIT tags produce estimates that are lower than the actual return of spring and summer Chinook Salmon to the Snake River Basin (Belnap et al. 2019). We used PBT data from the LGD fish trap coupled with the PIT tag conversion rate estimates from Bonneville Dam to LGD to estimate Chinook Salmon abundance at Bonneville Dam. The PBT estimate at LGD for each release site was divided by the age-specific (i.e. jacks and adults calculated separately) PIT tag conversion rate for that release site to calculate the escapement estimate at Bonneville Dam.

The estimated return for the combined Clearwater River basin release groups was 74\% of the preseason forecast. For the combined Salmon River release groups, the estimated return was $95 \%$ of the preseason forecast. Comparisons for individual release groups were variable but generally ranged from $28-148 \%$ of the preseason forecasts. The total adult return to Bonneville dam was $84 \%$ of the total adult forecast (Table 11).

Table 11. Comparison of forecasted and actual returns of adult (two- and three-ocean age only) Chinook Salmon to Bonneville Dam in 2019.

| Release hatchery | Release site | Forecast | Adult return |
| :---: | :---: | :---: | :---: |
| Clearwater | Selway River | 2,555 | 2,080 |
|  | Powell | 939 | 486 |
|  | NF Clearwater R. | 2,344 | 649 |
|  | Mill Creek | 74 | 26 |
|  | Red River | 2,391 | 2,790 |
|  | Clear Creek | 2,697 | 2,095 |
| Total Clearwater River |  | 11,000 | 8,126 |
| Rapid River | Rapid River Fish Hatchery | 11,014 | 8,177 |
|  | Little Salmon River | 741 | 547 |
|  | Hells Canyon Dam | 166 | 65 |
| Pahsimeroi | Pahsimeroi Fish Hatchery | 562 | 735 |
| Sawtooth | Sawtooth Fish Hatchery | 1,191 | 1,758 |
|  | Yankee Fork | 162 | 161 |
| McCall | Knox B. | 2,722 | 3,625 |
| Total Salmon River |  | 16,558 | 15,068 |
| Total |  | 27,558 | 23,194 |

Once PBT escapement estimates were derived for Bonneville Dam, we added those estimates to the release group and age specific harvest estimates from the lower Columbia River sport and commercial fisheries to estimate adult escapement to the Columbia River mouth (Table 12). We are aware that in addition to harvest mortality, substantial non-harvest mortality may occur in the lower Columbia River from pinniped predation with predation rate estimates ranging from 20\%-44\% between 2010 and 2015 (Wargo Rub et al. 2019). We did not attempt to incorporate this mortality into our Columbia River mouth escapement estimates, because the future of this work is uncertain, and estimates of non-harvest mortality may not be available for use in all years. Additional discussion of non-harvest mortality and predation effects can be found in Wargo Rub et al. (2019).

## 2019 LGD Trap Operation for Spring/Summer Chinook Salmon

Chinook Salmon were trapped five days per week (Mon-Fri) at LGD at a rate of $28 \%$ from April 5 through August 17. In 2019, the trap at LGD was opened later than previous years because of unplanned repairs and maintenance. Tissue samples were collected at specific rates based on the presence or absence of an adipose fin. The goal for ad-clipped Chinook Salmon was to collect approximately 2,000 samples throughout the run. To achieve this, a subsample rate was set at 33.3\% from April 5 to August 17. The goal for unclipped Chinook Salmon was to collect tissue samples from all fish collected in the adult trap. Samples collected from unclipped Chinook Salmon were part of an ongoing study to estimate the stock composition of the natural return (see Camacho et al. 2019). Because it is impossible to visually distinguish natural from unclipped hatchery Chinook Salmon, all the unclipped fish that were sampled were analyzed using PBT. As a result, the sample rate for the unclipped hatchery group was higher than for the clipped hatchery group (Table 10). Duplicate samples were not removed from this analysis, because fish that were sampled more than once were likely fish that had fallen back over the dam, reascended the adult ladder, and were counted more than once in the window count.

Throughout the 2019 adult return, tissue samples were collected from 10.6\% of the adclipped Chinook Salmon return and $21.8 \%$ of the unclipped hatchery return (Table 13).

Table 13. Estimated escapement of clipped and unclipped hatchery Chinook Salmon and summary of time stratification and sampling scheme for the 2019 adult migration at Lower Granite Dam. Samples included in analysis exclude samples that failed to genotype.

|  | Strata | Date range | Chinook <br> salmon <br> escapement | Samples <br> collected | Samples <br> included in <br> analysis | escapement <br> included in <br> analysis |
| :--- | :---: | :---: | ---: | ---: | ---: | ---: |

## Partitioning Window Counts to Stock and Age

Abundance of adult Chinook Salmon returns to LGD by stock and age were estimated post-season using the salmonid compositional bootstrap intervals (SCOBI) method (Steinhorst et al. 2017; Camacho et al. 2017). The age structure and fate of the clipped and unclipped samples are reported in Table 14.

Table 14. Summary of the age structure of clipped and unclipped hatchery origin Chinook Salmon sampled at Lower Granite Dam in 2019.

|  | BY |  | BY |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Origin | $\mathbf{2 0 1 6}$ | BY 2015 | $\mathbf{2 0 1 4}$ | Unassigned | Failed to genotype | Total |
| AD-clipped | 492 | 1,640 | 135 | 101 | 6 | 2,374 |
| Unclipped | 52 | 365 | 31 | 13 | 8 | 469 |

An estimated 24,434 hatchery Chinook Salmon migrated upstream of LGD during the spring/summer management period in 2019, including 22,191 ad-clipped and 2,096 unclipped fish. A total of 7,694 fish were from the Clearwater River basin, 14,051 were from the Salmon and Snake river basins, 2,451 were from Oregon and Washington, 91 were fall Chinook Salmon, and 147 fish were classified as unknown as a result of samples that did not assign back to the PBT baseline (Table 15).

Table 15. Estimates (bootstrapped $90 \%$ confidence intervals) by brood year and release site for returns of adult Chinook Salmon to Lower Granite Dam in 2019 based on SCOBI analysis.

a Includes smolts released into the mainstem Clearwater River in 2015 because of high TDG levels in the NF Clearwater.
b These releases are combined in previous years into a single release estimate at Clear Creek.
c Estimate includes releases at Little Salmon River and Hells Canyon Dam.
d Reared at Sawtooth Hatchery and released at Pahsimeroi Hatchery.
e Unknown hatchery Chinook that did not assign to the parental baseline. Estimate includes clipped and unclipped Chinook Salmon.

## Comparison of PIT Tag and PBT Return Estimates to Lower Granite Dam

PIT-tagged hatchery Chinook Salmon have been used since 2008 as a management tool to estimate returns to LGD. In season, these estimates help managers prioritize fisheries and broodstock acquisitions while post season, they provide estimates of smolt-to-adult survival and return rates. However, PIT tags have limitations and can misrepresent untagged fish due to tag loss and differential survival of tagged and untagged fish (Cassinelli et al. 2012). Underrepresentation of untagged returns by PIT-tagged fish has been an ongoing issue, and starting in return year 2012, with the implementation of PBT and adult sampling at LGD, we have an alternative method to estimate release site- and age-specific returns at LGD, which provides the ability to evaluate PIT tag representation.

We compared the percent of the PBT estimates at LGD that were accounted for by PIT tags for each release site by age (Equation 2). For 2019 returns, PIT tag estimates accounted for $69 \%$ of the PBT-based estimates at LGD across all age groups and release sites combined (Table 16). The $31 \%$ underrepresentation across all groups equated to 7,196 hatchery Chinook Salmon that were unaccounted for with PIT tags.

Equation 2. Age and release site specific PIT tag representation calculation using PIT tag estimates and PBT estimates.

$$
\% \text { PIT tag representation by age and release site }=\frac{\text { Age specific end of season PIT Estimate }}{\text { Age specific end of season PBT Estimate }}
$$

For this analysis, we assumed that the PBT estimates, which are based on the window count, are unbiased in this estimate of unaccounted Chinook Salmon. In reality, this estimate is likely biased high, because current methodology used to estimate escapement over LGD using PBT does not account for fallback, re-ascension, or night passage (i.e. fish that pass after counting hours end) that is detectable using PIT tags. The fallback with re-ascension rate is generally higher than the night passage rate; therefore, the window count is often an overestimate of Chinook Salmon escapement. This translates to negatively biased PIT tag representation estimates. For all release sites combined, PIT tag estimates represented the PBT estimates at a higher rate for the brood year 2014 cohort (80\%) than the brood year 2016 cohort (75\%) and the brood year 2015 cohort (67\%).

Table 16. Comparison of release site and brood year specific returns to LGD in 2019 based on PIT tag estimates and PBT analysis.

## Fallback / Re-ascension Rates and After-Hours Passage Rates at Lower Granite Dam

Fallback with re-ascension and after-hours passage rates are sources of bias in the window count at Lower Granite Dam. The rate at which these two actions occur are of interest because fallback with re-ascension results in fish being counted more than once in dam window counts (overestimate), while fish passing the counting window after counting hours results in some fish not being counted (underestimate). Chinook Salmon migrating upstream of LGD can fallback through one of four main routes: over the spillway, through the lock, through the juvenile bypass system, or through a turbine. We defined fallback with re-ascension as a Chinook Salmon that ascended the adult ladder more than once. Ascension and re-ascension events are assessed using the detailed interrogation history for individual PIT-tagged adults. We defined after-hour passage as fish that were detected in the adult ladder outside of the normal counting hours (04002000). Because the counting window is downstream of all PIT tag detectors in the LGD adult ladder, fish detected in the adult ladder in the first 15 minutes after the counting period ended were excluded from the after-hours estimate, while fish detected within the first 15 minutes of the counting period starting were counted as having passed after hours.

We estimated the fallback with re-ascension rate and after-counting-hours passage rate by release site for adults and jacks returning to LGD in 2019 (Tables 17 and 18).

Table 17. Fallback with re-ascension rates for PIT-tagged jack and adult Chinook Salmon by release site at Lower Granite Dam in return year 2019 with return year 2018 rates for comparison.

| 2019 TOTAL | $\mathbf{2 5 2}$ | $\mathbf{7}$ | $\mathbf{2 . 8 \%}$ | $\mathbf{5 1}$ | $\mathbf{0}$ | $\mathbf{0 . 0 \%}$ |
| 2018 TOTAL | $\mathbf{4 1 2}$ | $\mathbf{2 4}$ | $\mathbf{5 . 8 \%}$ | $\mathbf{7 4}$ | $\mathbf{4}$ | $\mathbf{5 . 4 \%}$ |

In 2019, the fallback with re-ascension rate was similar for adults and lower for jacks compared to 2018. More importantly, the fallback with re-ascension rate was higher than the after-counting-hours passage rate for adults and jacks suggesting that the window count likely overestimated Chinook Salmon escapement above LGD in 2019.

The net difference between fallback with re-ascension rates and after-hours passage resulted in the hatchery origin adult count at the LGD window being overestimated by 1,369 fish and the hatchery origin jack count being overestimated by 440 fish in 2019. However, PIT tags cannot be used to directly assess the frequency of fallback that does not result in re-ascension or the rate of passage through the lock. It is unknown to what extent these passage scenarios have on the overall window counts each year.

## Sport Fisheries in Idaho

In 2019, recreational fisheries for Chinook Salmon were conducted in several rivers, and Tables 19 and 20 list the location and duration of fisheries. Bank effort made up a greater proportion of the angler effort than boat effort for spring and summer Chinook Salmon fisheries, and boat effort was higher than bank effort in the fall Chinook Salmon fisheries (Table 21).

The highest catch rate for Chinook Salmon occurred in the Lower Salmon River (17 hours/fish), and the highest catch rate for Chinook Salmon kept occurred in the Lower Salmon Fishery (18 hours/fish). The overall catch rate was higher in the spring and summer Chinook Salmon fishery ( 21 hours/fish caught) than the catch rate in the fall Chinook Salmon fishery (51 hours/fish caught).

Returns of spring and summer Chinook Salmon in 2019 to Idaho contributed to a combined non-tribal harvest of 641 adults and 55 jacks which resulted in an adult harvest rate of $3.9 \%$ and a jack harvest rate of $1.3 \%$. Harvest shares for the Lower Salmon River, the Little Salmon River, and the Clearwater River fisheries were based on in-season PIT tag conversions between Bonneville Dam and LGD and the in-season PBT adjusted PIT tag estimate at LGD. The age-and release-site specific harvest rates and the overall age-specific harvest rates reported in Table 22 were calculated using equations 3 and 4.

Equation 3. Estimate of age and release group specific harvest rates for sport fisheries in Idaho.

Age and Release Site Specific Harvest Rate $=\frac{\text { Age and Release Site Specific Harvest Estimate }}{\text { Age and Release Site Specific PBT Estimate at LGD }}$

## Sport Fishery Catch Composition

During creel surveys, harvest estimates were generated for jacks (one-ocean) and adults (two- and three- ocean) separately based on the lengths of Chinook Salmon sampled. For mixedrelease site fisheries (e.g., Clearwater and lower Salmon), jack and adult harvest estimates were decomposed into release group and age specific estimates using PBT data obtained from tissue samples. The PBT data from each river section were expanded by release group-specific tagging rates, and the proportion of each release group and age in the PBT-based composition was applied to the jack and adult harvest estimates to generate final harvest estimates by fishery, release group, and age. There were five tissue samples collected and analyzed from the Clearwater River fisheries and 229 samples from the Salmon River fisheries. Harvest in the Little Salmon River fishery was assumed to be from the Rapid River release site. The age determination was based on length-frequency analysis of harvested fish checked during creel surveys (Table 23).

Table 23. Summary of 2019 spring/summer Chinook Salmon sport harvest in Idaho by fishery, release site, and ocean age.

| Fish hatchery and release site | One-ocean | Two-ocean | Three-ocean | Total |
| :---: | :---: | :---: | :---: | :---: |

a Unassigned fish were assumed to be natural origin.

## Hatchery Trap Returns

In 2019, 9,539 Chinook Salmon were trapped at hatchery weirs operated by IDFG. We estimated the age composition of adults returning to individual hatchery facilities using known age information obtained from CWTs and PIT tags in returning adults, and PBT samples collected from broodstock. After compiling the known age information, the statistical computer program $R$ ( $R$ Development Core Team 2010) was used with the mixdist library package (Macdonald 2010). The Rmix package was designed to estimate the parameters of a mixture distribution with overlapping components, such as the overlapping length distributions associated with adult salmon returns composed of multiple age classes and applies the maximum likelihood estimation method to a population based on a known age subsample (Table 25).

Table 25. Summary of adult spring/summer Chinook Salmon returns to IDFG hatchery racks, by trap, sex, age, and origin for return year 2019. At the Red River/ Crooked River, Powell, and Rapid River trapping facilities, sex is not determined at trapping, so only the number of jacks trapped and the number of adults trapped are reported.

| Trap | Origin | Males |  | Females ${ }^{\text {a }}$ | Total return |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Jacks | Adults |  |  |

| Total |  |  |  |  | 9,539 |

## Annual LSRCP Program Performance

Adult mitigation goals for facilities operated by IDFG are calculated using returns from smolt releases only. Adult returns in 2019 did not meet mitigation goals established by LSRCP. Escapement above Lower Granite Dam was 5,928 at Clearwater Fish Hatchery, 3,136 at McCall Fish Hatchery, and 2,077 at Sawtooth Fish Hatchery, which equated to $50 \%$ of the Clearwater Fish Hatchery mitigation goal, 39\% of the McCall Fish Hatchery mitigation goal, and $26 \%$ of the Sawtooth Fish Hatchery mitigation goal (Appendix A).

## ACKNOWLEDGEMENTS

We thank the many folks who contributed to the material in this report. Thanks to the hatchery managers and their staff for all their efforts to collect data and adapt to ever-changing requests. Thanks to the PSMFC marking crew for their efforts in marking and tagging fish. Thanks to the staff at the Eagle Fish Genetics Laboratory for coordinating the PBT project and providing it as a monitoring and evaluation tool. Thanks to IDFG regional staff who supplied harvest information, including Don Whitney, Josh Poole, Paul Janssen, and Brent Beller. Thanks to Joseph Feldhaus from ODFW for providing PIT tag estimates for Northeast Oregon release groups. Thanks to Brian Leth, Rod Engle, Stuart Rosenberger, and Chris Sullivan for providing draft edits and feedback on the content of this report. Thanks to Cheryl Leben for providing formatting and editing. Additional funding for PBT projects was provided by the Bonneville Power Association and data resulting from those projects contributed to some of the analyses included in this report.

#### Abstract

This annual report provides a summary of brood year 2013 (BY13) Chinook Salmon Oncorhynchus tshawytscha released from Lower Snake River Compensation Plan (LSRCP) and Idaho Power Company (IPC) hatcheries operated by the Idaho Department of Fish and Game (IDFG).

Idaho-LSRCP (McCall [MFH], Clearwater [CFH], Sawtooth [SFH]), IPC (Rapid River [RRFH], and Pahsimeroi [PFH]) fish hatcheries collected 12,221,526 green eggs in 2013 and released $9,261,543$ smolts in 2015. All facilities met their production targets for green egg take except for Pahsimeroi. Facilities faced minor fish health issues, the most prevalent being bacterial kidney disease (BKD), which resulted in the culling of low numbers of eggs from production. None of the fish health issues affecting BY13 Chinook Salmon resulted in significant losses to production.

Representative groups of juveniles from each facility were PIT tagged to estimate survival from release to Lower Granite Dam (LGD). Estimated juvenile survival rates during the 2014 migration ranged from $43 \%$ at the Yankee Fork to $82 \%$ at Rapid River. The weighted average juvenile survival to LGD across all IDFG release groups was 70\%.

BY13 adult Chinook Salmon returned from 2016 through 2018. Adult returns are summarized by age and release site for each hatchery and include estimates of harvest (ocean, downriver, and terminal), below-weir dropouts, and escapement. Hatchery-origin Chinook Salmon released from LSRCP and IPC hatcheries in Idaho were harvested in tribal and non-tribal fisheries in the Columbia and Snake rivers downstream of LGD and in mainstem and tributary fisheries upstream of LGD. The number of each hatchery's brood year-specific adult return that was harvested below LGD ranged from 111 fish for MFH to 2,263 for RRFH, with a total of 3,835 fish for all BY13 Chinook Salmon. The number of each hatchery's return to LGD that was harvested above LGD ranged from 26 fish for PFH to 4,656 for RRFH, with a total of 6,608 for all BY13 Chinook Salmon.

Brood year 2013 smolt-to-adult survival rates (SAS) ranged from 0.11\% for the Pahsimeroi Ponds release to $0.70 \%$ for Rapid River releases. Brood year 2013 smolt-to-adult returns (SAR) ranged from $0.08 \%$ for the Pahsimeroi Ponds release to $0.49 \%$ for the Rapid River release (Table 29). Estimates of SAS were lower than the recent five-year average for all facilities and estimates of SAR were greater than the recent five-year average at Sawtooth, and less than the recent fiveyear average at Clearwater, Rapid River, McCall, and Pahsimeroi. Progeny-to-parent ratios (PPR) to the project area ranged from 0.90 at PFH to 5.28 at RRFH.

## INTRODUCTION

The primary purpose of this report is to summarize activities at each of the Lower Snake River Compensation Plan (LSRCP)- and Idaho Power Company (IPC)-funded spring/summer Chinook Salmon fish hatcheries operated by the Idaho Department of Fish and Game (IDFG) and to estimate at what level each facility contributed to various adult return components. These include fisheries in the Pacific Ocean and Columbia River as well as the adult return upstream of Lower Granite Dam (LGD), the contributions to fisheries within Idaho, and the numbers of fish back to the respective hatchery trapping facilities. Additionally, life stage specific post-release survival is reported to address overall survival from release to return. In each annual report, a given brood year is summarized by consolidating the spawning, juvenile rearing and release information, and the adult returns from that particular brood year. Because of the five-year generation length of Chinook Salmon and the additional two years required to obtain all downriver harvest information, there is a seven-year lag associated with summarizing the productivity of a brood year. Hence, BY13 is finalized in the current 2019 report so that reporting is caught up to the most recent brood year that can be summarized.

## Spawning and Egg Eye-Up

Spawning was conducted across all spring/summer Chinook Salmon facilities in August and September 2013. Prespawn mortality was higher than the recent five-year average at McCall and Rapid River fish hatcheries, and lower than the recent five-year average at Sawtooth, Pahsimeroi, and Clearwater fish hatcheries. Prespawn mortality was higher for females than males at all facilities except Clearwater Fish Hatchery (Appendix A).

Average fecundity for each facility/spawning location was calculated using equation 5. Average fecundity ranged from 3,590 eggs per female at Rapid River Fish Hatchery to 4,876 eggs per female at Sawtooth Fish Hatchery (Table 23). Variation in fecundity between facilities in 2013 can be largely explained by the run type (spring vs. summer) of the fish at the facility. Fecundity was lower at facilities with spring Chinook Salmon programs (SF Clearwater and Rapid River), while facilities with summer Chinook Salmon programs (McCall and Pahsimeroi) had higher fecundities. Brood year 2013 fecundity was less than the 5 -year average fecundity for each facility (Appendix A).

Equation 5. Calculation of average fecundity.

$$
\text { Average Fecundity }=\frac{\# \text { Females Spawned }}{\# \text { Total Green Eggs Collected }}
$$

The green egg takes at all facilities except Pahsimeroi Fish Hatchery met or exceeded the level needed to fill the hatcheries to production targets in 2013 (Table 26). Culling occurred at all facilities. The number of fish culled in 2013 was less than the recent five-year average at all facilities except Pahsimeroi Fish Hatchery (Appendix A).

Table 26. Brood year 2013 spring/summer Chinook Salmon hatchery survival and production metrics for LSRCP and IPC hatcheries operated by IDFG.

| Fish hatcheryl stock | Male prespawn Mortality \% | Female prespawn Mortality \% | \# Males spawned | \# Females spawned $^{\text {a }}$ | Fecundity | Inventory ${ }^{\text {b }}$ | Disease ${ }^{\text {c }}$ | Total green eggs collected ${ }^{\text {d }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Sawtooth | 1.5\% | 2.1\% | 484 | 484 | 4,876 | 3 | 6 | 2,359,853 |
| SF Clwtr | 4.8\% | 0.9\% | 623 | 700 | 3,651 | 8 | 7 | 2,555,350 |
| Table 26 Continued. |  |  |  |  |  |  |  |  |
| Powell | 2.5\% | 0.0\% | 7 | 7 | 3,507 | 0 | 5 | 24,549 |
| Rapid R. | 5.1\% | 10.4\% | 1,057 | 1,057 | 3,590 | 0 | 47 | 3,794,677 |
| Pahsimeroi | 1.1\% | 3.6\% | 242 | 242 | 4,300 | 0 | 23 | 1,040,600 |
| Total or (Mean) | 5.8\% | 8.9\% | 2,960 | 3,037 | $(4,024)$ | 11 | 99 | 12,221,526 |

${ }^{\text {a }}$ Total females spawned includes those females whose eggs were later culled.
Females culled because of excess egg inventory.
c Females culled because of disease concerns.
d Total Green Eggs Collected may include eggs that were later culled and often includes eggs that were later transferred to another facility or organization. For numbers of eggs collected for hatchery-specific smolt releases, see Table 27.

## Green-Egg-to-Release Survival

The number of green eggs collected, percent eye-up, number of eyed eggs, smolts released, and green-egg-to-release survival rates at each facility for BY13 are summarized in Table 27. The average percent eye-up was $90.6 \%$, and the average green-egg-to-smolt survival rate was 80.9 \% across all facilities.

Table 27. Egg collection and survival metrics for brood year 2013 Chinook Salmon collected at LSRCP and IPC hatcheries operated by IDFG.

|  | \# green eggs collected <br> for smolt production | Eye up <br> rate | Yearling <br> \# eyed eggs | smolts <br> released | Green egg to <br> smolt survival |
| :--- | ---: | ---: | ---: | ---: | ---: |

## Fish Health

Fish health sampling occurred during both the spawning process and the rearing cycle. To screen for bacterial kidney disease (BKD), kidneys from adult female Chinook Salmon were visually inspected by fish pathologists and a kidney sample was taken to the Eagle Fish Health Laboratory for analysis using the enzyme-linked immunosorbent assay (ELISA) method (Dixon 1987). Female disease culling occurred on the "table" (i.e. at the time of spawning) if pathologists observed granulomas in a female's kidney or after spawning once ELISA values were available. Pathologists recommended culling any females with ELISA values above 0.25 optical density (Munson et al. 2010). Routine sampling of juveniles occurred 6 months prior to release and foursix weeks prior to release. Additional sampling occurred if symptoms or increased mortality was
documented earlier in the rearing cycle. Fish health staff screen for Aeromonas spp., Renibacterium salmoninarum (causative agent of BKD), Myxobolus spp. (causative agent of whirling disease), and Ichthyophthirius multifiliis (causative agent of "Ich"). Adults held for broodstock at all facilities were treated with formalin during holding.

## McCall Fish Hatchery

Routine inspections detected $R$. salmoninarum, resulting in the culling of eggs from 11 females. No pathogens were detected during the juvenile rearing cycle, and no major losses occurred as a result of fish health concerns.

## Sawtooth Fish Hatchery

After spawning, ELISA testing of kidney samples resulted in the culling of six females. Environmental Gill Disease, and Flavobacterium columnare were detected during the juvenile rearing cycle, but no major losses were documented because of disease or fish health concerns.

## Clearwater Fish Hatchery

Routine inspections detected $R$. salmoninarum, resulting in the culling of eggs from seven females in the South Fork Clearwater stock and five females in the Powell stock. Pre-release sampling did not detect any of the primary pathogens of concern for any stock reared at Clearwater Hatchery. No major losses occurred because of fish health concerns.

## Rapid River Fish Hatchery

Recycled fish were not injected or anesthetized during handling. Routine inspections detected $R$. salmoninarum, resulting in the culling of eggs from 47 females. Myxobolus species, Infectious Hematopoietic Necrosis (IHN) virus, Aeromonas species, and external mycosis were documented during the rearing cycle, but no major losses occurred because of fish health concerns.

## Pahsimeroi Fish Hatchery

Routine inspections detected $R$. salmoninarum resulting in the culling of eggs from 23 females. Bacterial Kidney Disease and Whirling Disease were detected during the rearing cycle, but no major losses were documented because of fish health concerns.

## Juvenile Releases

During the spring of 2015, 9,261,543 BY13 spring and summer Chinook Salmon smolts were released from three LSRCP and two IPC fish hatcheries located in Idaho. McCall and Clearwater fish hatcheries met or exceeded their smolt release goal while Sawtooth, Pahsimeroi, and Rapid River fish hatcheries did not meet their smolt release goals (Table 28). Direct and volitional release strategies were employed depending on facility design and the presence of acclimation ponds. Most of the Chinook Salmon from BY13 were adipose fin clipped to provide harvest opportunities in mark selective fisheries; however, some fish were released without adipose clips for supplementation and broodstock management purposes. Passive integrated transponder (PIT) tags were present in a portion of most release groups to provide juvenile survival estimates to LGD and adult escapement estimates. A proportion of certain release groups were also coded wire tagged to meet different management objectives (e.g., weir management,
broodstock management, supplementation, indicator stock harvest rates). The weighted average size at release for BY13 smolts (16.6 fish per pound; FPP) was larger than the recent five-year average of 18.6 FPP (Appendix D).

Table 28. Release details of brood year 2013 Chinook Salmon released in 2015 from LSRCP and IPC facilities operated by IDFG.

totals.

## Juvenile Migration Timing and Survival

Representative groups of Chinook Salmon from all hatcheries were PIT tagged to evaluate migration timing and survival to LGD. These metrics are summarized for all PIT-tagged smolts from BY13 released in 2015 (Table 29). Similar to previous years, the majority of PIT-tagged Chinook Salmon smolts arrived at LGD between mid-April and mid-May.

In migration year 2015, juvenile survival estimates to LGD ranged from $43 \%$ at the Yankee Fork release site to $82 \%$ at the Rapid River release site. Migration year 2015 juvenile survival rates were greater than the five-year average at Rapid River, McCall, Pahsimeroi, and Sawtooth, fish hatcheries and they were less than the five-year average at Clearwater Fish Hatchery (Appendix D).

Table 29. Estimated survival, migration, and arrival timing of brood year 2013 Chinook Salmon smolts at Lower Granite Dam (LGD) from releases at LSRCP and IPC fish hatcheries located in Idaho.

| Rearing fish hatchery | Release site | Distance to LGD (km) | \# PIT <br> tagged | \# Unique detections at LGD | Survival rate to LGD (95\% CI) | Detection probability | 50\% arrival date | 80\% arrival period (\# of days) |

## Adult Returns and Harvest Information

In this section, we report the adult return estimates and harvest estimates from BY13. We report adult returns to evaluate program performance (i.e. total adults produced) in Table 30, and we report harvest estimates by river section in Table 31 to summarize the distribution of harvest benefits between the Pacific Ocean and the Project Area (i.e. above LGD).

Beginning in brood year 2011, adult escapement estimates at LGD are based on PBT estimates. Escapement estimates to Bonneville Dam were calculated by dividing the age and release site specific PBT escapement estimates to LGD by age and release site specific PIT tag conversion rates from Bonneville to LGD. Loss in this table refers to fish that did not convert from Bonneville Dam to Lower Granite Dam as result of harvest, natural mortality or straying (Equation 6). Harvest estimates are based on expanded CWT recoveries collected during creel surveys and in catch samples. The total adult return was calculated by adding harvest in the ocean, harvest in the lower Columbia River fisheries below Bonneville Dam, and the PBT estimate at Bonneville Dam (Equation 7; Table 30).

Equation 6. Estimate of Chinook Salmon that were harvested, that strayed, or that died of natural mortality between Bonneville Dam and Lower Granite Dam from brood year 2013 in return years 2016-2018.

Loss Between Bonneville and LGD = Bonneville PBT Estimate - LGD PBT Estimate
Equation 7. Estimate of brood year 2013 Total Adult Return from return years 2016-2018.
Total Adult Return $=$ Harvest below Bonneville Dam + Bonneville PBT Estimate

Table 30. Estimated harvest and escapement of hatchery-origin Chinook Salmon from brood year 2013.

A main focus of the LSRCP and IPC mitigation programs is producing Chinook Salmon for harvest in Columbia and Snake river fisheries. Adult returns from BY13 provided harvest opportunities in both tribal and non-tribal fisheries in 2016, 2017, and 2018 including 5,210 fish harvested in fisheries downstream of Lower Granite Dam and 6,608 fish harvested in fisheries above LGD (Table 31). Based on the total return, Rapid River had the highest harvest rate and McCall had the lowest. Overall, 29\% of the total adult return from IDFG facilities was harvested by tribal fishers, sport anglers, and commercial fishers. Anglers harvested $23 \%$ of the return above LGD with the majority of that harvest attributed to anglers in Idaho.

Table 31. Returns, estimated harvest, and harvest rates above and below Lower Granite Dam from brood year 2013 Chinook Salmon released from Idaho Power Company and Lower Snake River Compensation Plan facilities in Idaho.

| Estimate location | Estimate type |  | Rapid River Fish Hatchery | Clearwater Fish Hatchery | Sawtooth Fish Hatchery | Pahsimeroi Fish Hatchery | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Ocean to Bonneville Dam | Harvest | 99 | 2,159 | 680 | 368 | 6 | 3,312 |

## Smolt-to-Adult Returns and Smolt-to-Adult Survival

Brood year 2013 smolt-to-adult survival rates (SAS) ranged from $0.11 \%$ for the Pahsimeroi Ponds release to $0.70 \%$ for Rapid River releases (Table 32). Brood year 2013 smolt-to-adult returns (SAR) ranged from $0.08 \%$ for the Pahsimeroi Ponds release to $0.49 \%$ for the Rapid River release (Table 32). Estimates of SAS were lower than the recent five-year average for all facilities and estimates of SAR were greater than the recent five-year average at Sawtooth Fish Hatchery, and less than the recent five-year average at Clearwater, Rapid River, McCall, and Pahsimeroi fish hatcheries (Appendix D).

Table 32. Brood year 2013 smolt-to-adult returns to LGD and smolt-to-adult survivals for all Chinook Salmon release groups from LSRCP and IPC hatcheries operated by IDFG.

| Fish <br> hatchery | Release site | Number <br> released | Returns <br> to LGD | Smolt-to-adult <br> returns (SAR) | Total returns <br> (basinwide) | Smolt-to-adult <br> survival (SAS) |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| McCall | Knox B. Seg | 867,469 | 1,835 | $0.21 \%$ | $0.32 \%$ |  |
|  | Knox B. Int | 254,817 | 771 | $0.30 \%$ | 0,768 | 092 |

## Progeny-to-Parent Ratio

Progeny-to-parent ratios reflect the number of adult returns (jacks excluded) that were produced for each parent spawned in 2013 for each facility. Progeny-to-parent ratios (PPRs) ranged from 1.33 at Pahsimeroi Fish Hatchery to 7.66 at Rapid River Fish Hatchery (Table 33).

Table 33. Progeny-to-parent ratios for brood year 2013 hatchery Chinook Salmon from LSRCP and IPC hatcheries operated by IDFG.

| Fish hatcheryl <br> stock | Total parents <br> (actual spawned + <br> prespawn morts) | Total progeny to <br> LGD (excluding <br> (jacks) | Progeny to <br> parent ratio <br> (project area) | Total progeny <br> (excluding <br> jacks) | Progeny to <br> parent ratio <br> (total) |
| :--- | :---: | :---: | :---: | :---: | :---: |
| McCall | 1,303 | 2,019 | 1.55 | 3,101 | 2.38 |
| Rapid River | 2,287 | 12,082 | 5.28 | 17,514 | 7.66 |
| Clearwater $^{\text {a }}$ | 1,790 | 5,921 | 3.31 | 9,609 | 5.37 |
| Sawtooth | 991 | 2,678 | 2.70 | 3,816 | 3.85 |
| Pahsimeroi | 574 | 519 | 0.90 | 761 | 1.33 |
| Total | $\mathbf{6 , 9 4 5}$ | $\mathbf{2 3 , 2 1 9}$ | $\mathbf{3 . 3 4}$ | $\mathbf{3 4 , 8 0 1}$ | $\mathbf{5 . 0 1}$ |

a Includes returns from the Red River, Selway River, and Clear Creek smolt releases. 'Total Parents' includes fish spawned at Rapid River and Kooskia whose eggs were transferred to Clearwater Hatchery to meet production needs.

## SUMMARY

## Spawning, Rearing, and Release

Spawning operations in BY13 produced sufficient numbers of green eggs to meet hatchery production targets at all facilities. Green-egg to smolt survival was lower than the five-year average at all facilities, which resulted in some facilities not meeting their smolt release goals. We released $9,261,543$ brood year 2013 smolts (101.4\% of the release goal) from IDFG facilities between March-April 2015 (Table 34).

Table 34. Juvenile release numbers compared to release targets for brood year 2013 hatchery Chinook Salmon from LSRCP and IPC hatcheries operated by IDFG.

| Fish hatchery | Smolt release target | Smolts released (BY2011) | Release \% of target |
| :--- | :---: | :---: | :---: |
| McCall | $1,000,000$ | $1,122,286$ | $112.2 \%$ |
| Rapid River | $3,000,000$ | $2,899,974$ | $96.7 \%$ |
| Clearwater | $2,335,000$ | $2,681,625$ | $114.8 \%$ |
| Sawtooth | $1,800,000$ | $1,729,449$ | $96.1 \%$ |
| Pahsimeroi | $1,000,000$ | 828,209 | $82.8 \%$ |
| Total | $9,135,000$ | $9,261,543$ | $101.4 \%$ |

## Adult Survival Rates

Mitigation goals for the three LSRCP-funded hatcheries outlined in this report are based on the expected number of adult returns given release targets were met and assumed survival rates were achieved. Because Idaho Power Company does not have adult mitigation goals, they are not reported here. To provide some measure of how the BY2013 releases performed relative to mitigation goals, we compared the SAS and SAR observed for the BY2013 releases at each facility to those needed to achieve annual mitigation objectives based on the smolt release targets for BY2013. None of the three LSRCP funded facilities achieved the SAS or the SAR needed to reach the basinwide adult mitigation objectives or the project area (above LGD) mitigation goals.

Table 35. Adult mitigation and actual return numbers for brood year 2013 hatchery Chinook Salmon from LSRCP facilities operated by IDFG.

|  | SAR to achieve | Brood year <br> 2013 actual | SAS to achieve <br> Sitigation goal | Brood year <br> 2013 actual <br> SAS |
| :--- | :---: | :---: | :---: | :---: |
| Fish hatchery | Saligation goal | SAR | $0.23 \%$ | $4.00 \%$ |
| Clearwater | $0.80 \%$ | $0.26 \%$ | $2.55 \%$ | $0.34 \%$ |
| Sawtooth | $0.51 \%$ | $0.22 \%$ | $5.40 \%$ | $0.40 \%$ |

## ACKNOWLEDGEMENTS

We would like to acknowledge the Pacific States Marine Fisheries Commission (PSMFC) and Idaho Power Company (IPC) for providing assistance with data collection and compilation. We thank all of the hatchery managers and their staffs for providing data. We thank Donald Whitney, Kim Apperson, Paul Janssen, and Brent Beller for providing sport harvest information and both the Nez Perce and Shoshone Bannock tribes for providing tribal harvest information. Thank you to Brian Leth, Rod Engle, Stuart Rosenberger, and Chris Sullivan for providing comments on the draft report and Cheryl Leben for providing formatting and editing.

a Age structure is based on Lower Granite Dam PBT estimates converted downstream to Bonneville Dam using age specific PIT tag conversion rates.

Appendix E. Number of juveniles released, size at release, juvenile survival to LGD, and SAR and SAS for smolts released from LSRCP and IPC facilities for brood years 1991 through 2013 by facility and by funding source. Adult returns to LGD are based on parentage-based tagging estimates from brood year 2011 forward.

Appendix F. Percentage of smolt release goals met at PFH and RRFH from 1991 through 2013.

Appendix G. Percentage of Chinook Salmon smolt release goals met at Lower Snake River Compensation Hatcheries in Idaho.

## Prepared by:

Matthew J. Belnap
Fisheries Biologist
Idaho Department of Fish and Game

Forrest Bohlen
Data Management Specialist
Pacific States Marine Fisheries Commission

Corey Dondero
Fisheries Technician
Pacific States Marine Fisheries Commission

Approved by:

James A. Chandler
Fisheries Program Supervisor
Idaho Power Company

John Cassinelli
Anadromous Fisheries Manager Idaho Department of Fish and Game
J. Lance Hebdon

Chief, Fisheries Bureau
Idaho Department of Fish and Game

Riley Brown
Fisheries Biologist
Idaho Power Company

[^0]:    a AD and ADint PIT numbers for these releases are combined in Table 3.
    b Chinook Salmon originally destined for Red River that were released into the NF Clearwater because of record high flows in Red River.

[^1]:    a The adult estimate from PIT tags is adjusted to only include adipose clipped returns.
    b Brood needs and non-tribal harvest shares are not identified for Chinook Salmon jacks.
    c Includes AD-clipped and UNC-hatchery estimates.
